INDEX

ABDOMINAL Scutes in the Round Herrings (Dussumieriidae) (P J P Whitehead), 511
Abelson, Dr Philip H Appointed editor of *Science*, 122
Abnormal Breeding Behaviour in the Oyster (Denis Key), 620
Abnormal Hydrographical Conditions in the Menai Straits (J G Harvey and C P Spencer), 794
Absence of Hæmoglobin A_2 in an Adult (P Fessas and G Stamatoyannopoulos), 1215
Absence of Natural Volatile Solvents in Cockroach Grease (A R Gilby), 729
Absorption-Elution Method of Grouping Blood-Stains (R A Outteridge), 818
Academic Press Cost of Books, 332
L'Académie Internationale d'Astronautique de la Fédération Internationale d'Astronautique D and F Guggenheim Medal awarded for 1962, 946
Acari (Terrestrial) of the British Isles An Introduction to their Morphology, Biology and Classification (G Owen Evans, J G Sheals and D Macfarlane), Vol 1, *review* by Prof Harry Hoogstraal, 527
Accelerated Lysis of Blood Clots (L Lorand and A Jacobsen), 911
Acephaline Gregarines Cultivation of *Eisenia fœtida* (Sav) Free from Infection with (H B Miles), 921
Acetoacetate on the Metabolism of Fatty Acids by the Perfused Rat Heart Effect of Pyruvate and (Robert E Olson), 597
Acetone Isotherms (G A Bottomley and T H Spurling), 900
Acetylacetone Complex of Platinum (II) Structure of a Carbon-Bonded (Dr B N Figgis et *al*), 1278
Acetylcholine a Central Transmitter ? (D R Curtis and P Andersen), 1105
Acetylcholinesterase Radiometric Assay of (F P W Winteringham and R W Disney), 1303
Acetylcholinesterase in Nerve Tissue Multiple Nature of (J Bernsohn et *al*), 285
N-Acetyl-dopamine as Sclerotizing Agent of the Insect Cuticle (P Karlson and C E Sekeris), 183
N-Acetylmuramic Acid and Penicillin as a Basis for Antibiotic Action A Structural Similarity between (J F Collins and M H Richmond), 142
Acid and Alkaline Media Dissolution of AgO in (J A McMillan), 594
Acid-Catalysed Reaction of Reduced Pyridine Nucleotides (I G Fels), 704
Acid Leaching of Thorium Carbide (Yasuichi Sasaki et *al*), 267
Acid Mucopolysaccharides of the Human Uterus (G Loewi and R Consden), 148
Acid Phosphatase Activity in Human Blood Cells (Arthur F Goldberg and Tibor Barka), 297
Acid Phosphatase in Human Prostatic Fluid Reversible Inactivation of (A Steens-Lievens and H J Tagnon), 400
Ackman, R G Revision of the End Carbon Chain Concept in the Gas-Liquid Chromatography of Methyl Esters of Unsaturated Fatty Acids, 1198
Acmaea limatula, to Abrupt Changes in Temperature Initial Response of the Heart-rate of a Gastropod (Prof Earl Segal), 674
Acred, P , et *al* Chemistry, Toxicology, Pharmacology, and Microbiology of a new Acid-stable Penicillin Resistant to Penicillinase (*BRL 1621*), 1264
Acrylamide Gel as an Electrophoresis Medium (Samuel Raymond, Masumi Nakamichi and Barbro Aurell), 697
Actinomyces israelii in Chemically Defined Media Growth of Several Strains of (A O Christie and J W Porteous), 408
Actinomycete Actinonin an Antibiotic Substance produced by an (J J Gordon et *al*), 701
Actinomycins on the Content of 17-Hydroxycorticosteroids in Guinea Pig Plasma Influence of (J Planelles et *al*), 713
Actinonin an Antibiotic Substance produced by an Actinomycete (J J Gordon, B K Kelly and G A Miller), 701
Action of 7,12-Dimethylbenz(alpha)anthracene on the Mitotic activity of normal and malignant Rat Fibroblasts *in vitro* (V B Starikova and J M Vasiliev), 42
Action of Ionizing Radiation on Rat Liver Cell Nuclei (G Scholes, J J Weiss and C M Wheeler), 802
Action of Manganese Dioxide on D-Fructose (G J Moody), 71
Activation of Endogenous Plasma Proteolytic Enzymes with the Consequent Production of Pharmacologically Active Polypeptides (Margaret MacKay, W d'A Maycock and B S Combridge), 1206
Active Transport of Sodium and Chloride by the Isolated Skin of the South American Frog *Leptodactylus ocelatus* (J A Zadunaisky and O A Candia), 1004
Adachi, T , et *al* Isolation of Tetramethylpyrazine from Culture of *Bacillus natto*, and Biosynthetic Pathways of Tetramethylpyrazine, 1103
Adam, J , et *al* Direct Conversion of Fission Heat to Electric Power, 65
Adam, N K Surface Activity The Physical Chemistry, Technical Applications, and Chemical Constitution of Synthetic Surface-Active Agents, second edition, revised and enlarged, *review*, 531
Adamanis, Prof Franciszek *Obituary* by Dr Danuta Malejka, 329
Adams, E P , et *al* Gastric-stimulating Factor in Meat Extract, 1207
Adams, Ernst W , and Robert M Huffaker Parent Body Hypothesis for Origin of Tektites, 681
Adaptation of *Escherichia coli* to Selenate (A Shrift and Ellen Kelly), 732
Adaptation of the Small Intestine to a High-Fat Diet containing Saturated and Unsaturated Fatty Acids (Z Slabochova and Z Placer), 380
Adaptations of the Mammalian Skin to the Aquatic Mode of Life (Dr W Sokolov), 464
Adelstein, S J Specific Radioprotective Effect of the Mitochondrial Matrix, 195
Adenosine Diphosphate Glucose and Glucoside Biosynthesis (J C Trivelloni, E Recondo and C E Cardini), 1202
Adenosine Triphosphatase Activity by Energy-Linked Pyridine Nucleotide Reduction in Mitochondria Control of Endogenous (Prof B Chance and Dr T Ito), 150
Adenosine Triphosphate Production by Calf Lens Homogenates Pathways of (P Mandel and J Klethi), 306
Adhesion (edited by Prof D D Eley), *review* by L R G Treloar, 3
Adrenal Cortex of Hypophysectomized Rats *In vivo* induced Oxidation by Adrenocorticotrophic Hormone of Reduced Pyridine Nucleotide in the (Prof B Chance, B Schoener and Dr J J Ferguson, jun), 776
Adrenal Gland Metabolically Linked Changes in Fluorescence Emission Spectra of Cortex of Rat Brain, Kidney and Adrenal Gland, (Prof B Chance et *al*), 1073
Adrenalectomy in Renal Tubular Necrosis Enzyme Leakage, Antihistamine Drugs and (R A Paz et *al*), 89
Adrenergic Neurone Blocking Agents Amidines as (A L A Boura, F C Copp and A F Green), 1213
Adrenergic Neurone Blocking Tropine Derivatives with Long-lasting Hypotensive Action (M Doda, L Gyorgy and K Nador), 1108
Adrenocorticotrophic Hormone of Reduced Pyridine Nucleotide in the Adrenal Cortex of Hypophysectomized Rats *In vivo* induced (Prof B Chance, B Schoener and Dr J J Ferguson, jun), 776
Adrian, The Rt Hon Lord *Obituary* of Prof P Hoffmann, 121
Advances in Cancer Research, Vol 6, (edited by Prof Alexander Haddow and Sidney Weinhouse), *review* by Dr W J P Neish, 418
Advances in Chemical Engineering, Vol 3, (edited by Thomas B Drew, John W Hoopes, jun , and Theodore Vermeulen), *review* by Prof J F Richardson, 1238
Advances in Inorganic Chemistry and Radiochemistry, Vol 3, (edited by H J Emeléus and A G Sharpe), *review* by D W A Sharp, 531
Advances in Quantum Electronics (edited by Prof Jay R Singer), *review* by Prof K W H Stevens), 316
Advances in Space Science and Technology, Vol 3, (edited by Frederick I Ordway, III), *review* by D G King-Hele, 1238
Advances in Virus Research, Vol 8 (edited by Kenneth M Smith and Max A Lauffer), *review* by N W Pirie, 213
Aedes aegypti (L) and *Aedes mascarensis* MacGregor in Mauritius A Case of Gene Survival Following Species Eradication ? (G A H McClelland and Raymond Mamet), 965
Aedes mascarensis MacGregor in Mauritius A Case of Gene Survival Following Species Eradication ? *Aedes aegypti* (L) and (G A H McClelland and Raymond Mamet), 965
Aerobic Respiration in Soil Crumbs (Dr D J Greenwood and G Berry), 161
Aerodynamics J R Busing appointed senior lecturer in the Department of, 24
Africa, A Social Geography (Anthony Sillery), *review* by Prof R W Steel, 214
Agar Gel Electrophoresis of Colicines in (P J Chapple), 1325
Age Differences in Cyclic Motor Reaction (Jaroslav Tejmar), 813
Age of Lundy Granite, Bristol Channel (M H Dodson and Dr L E Long), 975
Age of the Earth's Crust and Lead Model Ages (J R Richards), 65
Age of the Lundy Granites (Dr J A Miller and F J Fitch), 553
Ageno, Mario Deoxyribonucleic Acid Code, 998
Aggregate Structure in Thin Nickel Films (Joel S Hirschhorn and Robert J Maciag), 169
AgO in Acid and Alkaline Media Dissolution of (J A McMillan), 594
Agricultural Research Council Elections, 233 , Radiobiological Laboratory report on Radioactivity in Diet (H M S O *ARCL* 7), 437
Agriculture Prof H S Darling appointed to the Samaru Institute for, 544
Agriculture The Economics of Subsidising (Gavin McCrone), *review* by Colin Clark), 318
Agrobacterium tumefaciens Fixed Pathogenic *L* Forms of (M Rubio-Huertos and R B M de Velasco), 101
Ahmadu Bello University, Northern Nigeria Appointment of Professor, Dean and Director of the Samaru Institute, 544
Ainscough, J B Effect of Adsorbent Temperature on the Brunauer-Emmett-Teller Surface Area determined by Krypton Adsorption at 77°K, 1089
Ainsworth, G C Longevity of *Schizophyllum* commune II, 1120

Ainsworth, L , and R H Common Crystalline Œstrone isolated from Urine of the Laying Hen, 77
Airborne Fission Product Radioactivity using Gamma-Ray Spectrometry Determination of (Dr P F Gustafson et *al*), 557
Airborne Transmission of Influenza Virus Infection in Mice (Jerome L Schulman and Edwin D Kilbourne), 1129
Aircraft Design K H Griffin appointed senior lecturer in the Department of, 24
Aircraft Mechanical Engineering Equipment Research and Development Director appointed, 860
Airglow Emission Intensity on October 28-29, 1961 Unusual Fluctuations of 5577A *01* (S M Silverman), 481
Akazawa, Takashi, et *al* Isolation of Esculetin from Sweet Potato Roots with Black Rot, 726
Alanine and Gamma-Aminobutyric Acid Levels in Rat Brains Influence of Various Stimuli on Lactic Acid (Michael Ruščak), 290
Albino Rats Spontaneous Hydronephrosis in (T Astarabadi and E T Bell), 392
Albumin/Globulin Ratio Endocrine Control of the Plasma (Cyril Beardwood, Christine Gilbert and Joseph Gillman), 710
Albumins in the Domestic Fowl Occurrence of Two Plasma (Dr W M McIndoe), 353
Alder and of *Rhizobium meliloti* B_{12} Coenzyme Content of the Nodules from Legumes, (Mark Kleiwer and H J Evans), 828
Aldridge William G Use of Indium Trichloride for the Separation of Native, Denatured and Single-stranded Deoxyribonucleic Acid, 284
Alexander, G V , and R E Nusbaum Zinc in Bone, 903
Alexander, Leroy E , and Sabri Ergun Crystalline Forms of Carbon A Possible Hexagonal Polymorph of Diamond, 765
Alfert, Max, and Nirmal K Das Sensitivity of Interphase Cells to Chromosome Breakage by X-rays, 302
Algæ The (Prof V J Chapman), *review* by Dr Mary Parke and G T Boalch, 212
Algology Proceedings of the Symposium on (edited by D Raghavan and P Kachroo), *review* by Dr J W G Lund, 419
AlH New Evidence for Free (C W Heitsch), 995
Aliphatic Amines Ultrasonic Relaxations in Aqueous Solutions of (J F McKellar and J H Andreae), 778
Alkaline Chloride Chemical Effects of Mechanical Dispersion of (Dr H M Papée and Dr G L Petriconi), 1183
Alkaline Degradation of 2-Methyl-1,4-Naphthoquinone An Electron Spin Resonance Study of the (Dr Thomas C Hollocher, jun , and Dr Morton M Weber), 247
Alkaline Hydrolysis of Penicillins Formation of 6-Aminopenicillanic Acid by (F R Batchelor and J Cameron Wood), 1000
Alkaline Media Dissolution of AgO in Acid and (J A McMillan), 594
Alkaline Phosphatase Activity in Endothelium of Arteries Localized Areas of High (Flaviu C A Romanul and Roger G Bannister), 611
Alkaline Phosphatase in Human Eccrine Sweat (L J A Loewenthal and W M Politzer), 902
n-Alkanes and Polyethylene Formation of Unsaturation and Cross-links in the Radiolysis of (Dr B J Lyons), 690
Alkylation as the Mechanism by which the Hepatotoxic Pyrrolizidine Alkaloids act on Cell Nuclei (C C J Culvenor, A T Dann and A T Dick), 570
Alleles in Diploid Pollen Interactions of *S* (K K Pandey), 205
Allen, L R , et *al* A Correlation between the Spectra of Non-thermal Radio Sources and their Brightness Temperatures, 692
Allen, Dr N P Properties of Reactor Materials and the Effects of Radiation Damage (Proceedings of the International Conference held in 1961), *review*, 317
Allergy in Man New Serological Test for (Prof W B Shelley), 1181
Allibone, Dr T E Release and Use of Atomic Energy (Based on the Royal Institution Christmas Lectures), *review* by K E B Jay, 213
Allison, A C , and T Nash Hydrogen Bonding and Charge-Transfer Complexes, 994
Allium cepa Cytoplasmic Localization of Deoxyribonucleic Acid in (P B Gahan, J Chayen and A A Silcox), 1115
Allium cepa L Possible Genetic Evidence of Somatic Segregation in (Elmo W Davis), 833
Allocation of Scientific Research in Britain, 209
Allotypic γ-Globulins in Antibodies Deletions of (Prof P G H Gell and Dr A Kelus), 44
Allotypy A Notation for (Dr S Dray et *al*), 785
Alloxan on the Insulin Content of Micro-dissected Mammalian Pancreatic Islets Effect of (P K Dixit et *al*), 388
Alnus and *Casuarina* Cobalt and the Fixation of Nitrogen by Root Nodules of (G Bond and E J Hewitt), 94
Alpha-Glucosidase Fermentation of Saccharose by (J Santa Maria), 1201
Alston, R E and Janiece Simmons Specific and Predictable Biochemical Anomaly in Interspecific Hybrids of *Baptisia viridis* X *B Leucantha*, 825
Alumina from a 'Hydrogen' Alunite Formation of (P T Davey and T R Scott), 376
Aluminium Hydroxide Sorption of Dissolved Phosphorus from Sea-water by Means of (B Newall), 72
Aluminium-Magnesium Alloy Characteristics of Fatigue-activated Creep in an (A J Kennedy), 898
Aluminium on Plant Growth Stimulative effects of (C Hackett), 471
Alveolar-Arterial P_{co_2} Discrepancy An (J William Poppell and Parker Vanamee), 809
American Association for the Advancement of Science (resignation of the editor of *Science*), 122
American Chemical Society The Ipatieff Prize awarded, 20
American Men of Science A Biographical Directory (edited by Jaques Cattell), The Physical and Biological Sciences, tenth edition, *review*, 107
American Oil Chemists' Society Annual Convention, 948
American Scientist, March 1962 (Dr W R Brode), 1
American Society for Cell Biology Second Annual Meeting, 1157
American Society for Quality Control The Shewhart Medal awarded, 20
Amides with Lithium Perchlorate Complex Formation of Monomeric (A F Diorio, E Lippincott and L Mandelkern), 1296
Amides N-H Stretching Frequencies of Amines and (A G Moritz), 800
Amidines as Adrenergic Neurone Blocking Agents (A L A Boura, F C Copp and A F Green), 1213
Amine-Chloranil Complexes Spectra of (M A Slifkin), 693
Amine Oxides with Radioprotectant Properties Complex (Thomas J Haley, et *al*), 1012
Amines and Amides N-H Stretching Frequencies of (A G Moritz), 800
Amines in Clover (*Trifolium alexandrinum*) after Incubation under Sterile Conditions Tyramine and Other (H Neumark), 626
Amines Ultrasonic Relaxations in Aqueous Solutions of Aliphatic (J F McKellar and J H Andreae), 778
Amino-Acid Composition of Gramicidin (Kiyoshi Okuda, Chin-Shin Lin and Prof Theodore Winnick), 1067
Amino-Acid of Phycoerythrins Methionine, the *N*-Terminal (P Ó Carra and C Ó hEocha), 173
Amino-Acids and Distribution of Radioactive Sulphur after Application of ^{35}S-labelled Amino-Acid Copolymers in the Rat Thermal Copolymerization of Protein Hydrolysates containing ^{35}S (G Krampitz and F Knappen), 385
Amino-Acids and Peptides Reaction of Fluoro-2,4-dinitrobenzene with (Brian L Tonge), 491
Amino-Acids and Proteins Oxygen Effect as an Explanation of Differences between the Action of α-Particles and X- or γ-Rays on Aqueous Solutions of (A J Swallow and J A Velandia), 798
Amino-Acids and Vitamins by Human Amnion Cell Cultures infected with a Tick-borne Encephalitis Virus Uptake of Glucose, (Dr P Halonen et *al*), 659
Amino-Acids in Corn-steep (Jan Zelinka, Marius Hudec and Libuše Pelcova), 503
Amino-Acids in Thymine-starved *Escherichia coli* Repression of β-Galactosidase Synthesis by (D Nakada), 1303
Amino-Acids of Isolated Calf Thymus Nuclei Free (Tung-Yue Wang), 1099
Amino-Acids The Branch Point in the Biosynthesis of the Aromatic (Dr M I Gibson et *al*), 1173
Inactivation of Egg-White Lysozyme by Ultrasonic Waves and Protective Effect of (Dr F M Dietrich), 146
γ-Aminobutyric Acid against Oxygen Toxicity Protective Action of (J D Wood and W J Watson), 296
Amino-nucleoside to produce Abnormalities in the Fœtus of the Rat Failure of (Jay Bernstein, Ruben Meyer and Donald S Pickman), 1209
6-Aminopenicillanamide and Methyl 6-Aminopenicillanate (B K Koe), 1200
6-Aminopenicillanic Acid by Alkaline Hydrolysis of Penicillins Formation of (F R Batchelor and J Cameron Wood), 1000
6-Aminopenicillanic Acid Penicillin-Like Substances in Preparations of (F R Batchelor et *al*), 954
Ammonia Toxicity and *p*H (Dr Kenneth S Warren), 47
Ammonium Nitrate Detonation in (Stewart Paterson and Jean M Davidson), 277
Amnion Cell Cultures infected with a Tick-borne Encephalitis Virus Uptake of Glucose, Amino-Acids and Vitamins by Human (Dr P Halonen et *al*), 659
Amorphous Carbons Effect of Oxygen on the Electron Spin Resonance Line-Widths of (J W C Spackman), 764
Amos, Harold and Katherine E Kearns Synthesis of 'Bacterial' Protein by Cultured Chick Cells, 806
Amphineura Stages in the Development of Viviparity in the (R K Dell), 512
An Alveolar-Arterial P_{co_2} Discrepancy (J William Poppell and Parker Vanamee), 809
An Annelid Proprioceptor (G A Horridge), 403
An Economical Prism System for Fast Spectrographs (N J Rumsey), 168
An Electron Microscopic Demonstration of a Surface Pattern on the Plasma Membrane of Sectioned Intestinal Epithelium after Saponin Treatment (A R Muir), 1023
An Electron Spin Resonance Study of the Alkaline Degradation of 2-Methyl-1,4-Naphthoquinone (Dr Thomas C Hollocher, jun , and Dr Morton M Weber, 247
An Elementary Interpretation of Science (Dr Michael C Cox *Understanding Science*, No 1), 132
An Equine Respiratory Virus with Enterovirus Properties (G Plummer), 519
An Evaluation of Controlled-Temperature Environments for Plant-Growth Investigations (Dr A Joffe), 1043
An Immunological Method for purifying Insulin for Radioactivity Determinations (K W Taylor, Valerie E Jones and G Gardner), 602
An Improved Intravital Dye Iron-Prussian Blue Method for the *in vitro* Examination of Living Lymphatic Vessels (F R Wells), 188
An Inhibitory Growth Correlation in the Apothecial Stipe of *Sclerotinia sclerotiorum* (Ruth M Henderson), 826
An Interpretation of the Transition in Composition of Soluble Lipoproteins (W H Cook), 1308
An Introduction to the Theory of Linear Spaces (Prof Georgi E Shilov), *review* by Prof P J Hilton, 842
An Isotope Effect in the Probability of ionizing a Molecule by Energy Transfer from a Metastable Noble-Gas Atom (William P Jesse and Robert L Platzman), 790
An Ultra-Rapid Scanning Fabry-Perot Interferometer (J Cooper and J R Greig), 371
Anæmic Anoxia on Erythropoiesis of Nephrectomized Dog Effect of (J P Naets and A F Heuse), 190
Anaerobic Metabolism of Mammalian Spermatozoa by Carbon Dioxide Initiation of (J R Lodge and G W Salisbury), 293
Anæsthesia and the Action of DDT on *Anopheles* Larvæ (S Friedman and J Chalkley), 1225
Anæsthetic on the Heart and Respiration of Teleost Fish Effect of an (D J Randall), 506
Analogies and Differences between Human and Horse Hæmoglobin (Pavel Masiar), 507
Analytical Chemistry in Nuclear Reactor Technology, Sixth Conference on, 1053
Ancient Iron Nails well preserved from Apparently Corrosive Soils (G H Booth A K Tiller and F Wormwell), 376
Ancient Monuments Board for England, Scotland and Wales eighth annual report, 438
Andersen, P , and D R Curtis Acetylcholine a Central Transmitter 1105
Anderson B , et *al* Brightness Distribution of the Radio Source 14*N*5*A*, 165
Anderson D A , and E S Freeman Differential Thermal Analysis of Potassium Perchlorate, 1297
Andersson, Ingvar, O , and Kurt Lidén Cæsium-134 in Man, 1040

INDEX

Andrade, Prof E N da C Flow of Cadmium under Very Small Stresses, 991 , Nuclear Power Today and Tomorrow, *review*, 633
Andreae, J H , and J F McKellar Ultrasonic Relaxations in Aqueous Solutions of Aliphatic Amines, 778 , Ultrasonic Relaxation in a Micellar System *n*-Octylamine-Water, 865
Angelici, R J , et *al* Isomerism of Disubstituted Manganese Pentacarbonyl Bromide, 993
Animal Husbandry and Hygiene Dr Roland Hill appointed to readership in, 440
Animals Brain and Muscle Potentials from the Intra-Uterine Fœtus in Unnarcotized, Conscious (R A M Bergstrom), 1004
Animals as Social Beings (Prof Adolf Portmann), *review* by J M Cullen, 635
Animals of Britain Nos 1–8, *review* by B J G Maitland, 109
Annals of the International Geophysical Year, Vols 21 and 22 I G Y Solar Activity Maps, DI and *D*II, *review* by Dr H von Kluber and Prof R O Redman, 1237
Annals of the South African Museum (46, Part 9, 1962), 22
Annual Review of Microbiology, Vol 15 (edited by Charles E Clifton in association with Sidney Raffel and Mortimer P Starr), *review* by Dr B A Newton, 934
Annual Review of Physical Chemistry, Vol 12 (edited by H Eyring in association with C J Christensen and H S Johnston), *review* by Dr A B Callear, 110
Annual Review of Physiology, Vol 24 (edited by Victor E Hall in association with Frederick A Fuhrman and Arthur C Giese), *review* by Prof D C Harrison, 635
Anomalous Excitation Processes in Flames and Detonations (A R Fairbairn), 695
Anopheles gambiae Giles Status of the East African Salt-water-breeding variant (H E Paterson), 469
Anopheles hyrcanus and Malaria in East China (*Chinese Medical Journal*, 81, No 2 , February 1962), 126
Anopheles Larvæ Anæsthesia and the Action of DDT on (S Friedman and J Chalkley), 1225
Anopheles Mosquitoes Three Months after Storage at —70° C Successful Dissection of the Salivary Glands of (P G Shute and M E Maryon), 89
Antagonism by Deoxyribonucleic Acid Extracts of the Growth Inhibitory Effects of 8-Azaguanine on Mammalian Cells in Culture (T R Bradley, R A Roosa and L W Law), 304
Antagonism of Bretylium by Sympathomimetic Amines (C Matsumoto and A Horita), 1212
Antarctic Biology Symposium on, 333
Antartico Argentino Publications of the Instituto, 124
Antibiotic Action A Structural Similarity between *N*-Acetylmuramic Acid and Penicillin as a Basis for (J F Collins and M H Richmond), 142
Antibiotic Activity of Various Types of Cannabis Resin (A Radošević, M Kupimc and Lj Grlić), 1007
Antibiotic Formation by Bromthymol Blue and other Indicators in *Streptomyces rimosus* Inhibition of (W A Zygmunt), 1102
Antibiotic Substance produced by an Actinomycete Actinonin an (J J Gordon et *al*), 701
Antibiotic Synergism Evaluation of (Dr D Kaplan and Dr W Koch), 958
Antibiotics Inhibition of Endotrophic Sporulation by (Thomas D Brock), 309
Antibodies Deletions of Allotypic γ-Globulins in (Prof P G H Gell and Dr A Kelus), 44
Antibody-binding Sites *In vivo* Isolation of *Hymenolepis nana* and (R M Coleman and N M Fotorny), 920
Antibody to Enzymes–A Three-Component System Meeting on, 654
Antifungal Activity of *Cylindrocarpon radicicola* Wr (N H White, G A Chilvers and G Evans), 406
Antigen-injected Mice Immunogenic Sub-cellular Particles obtained from Spleens of (Robert E Franzl), 457
Antigens induced by Paralysing Doses of Bovine Serum Albumin Unresponsiveness to Unrelated (P Liacopoulos, B N Halpern, F Perramant), 1112
Antihistamine Drugs and Adrenalectomy in Renal Tubular Necrosis Enzyme Leakage, (R A Paz et *al*), 89
Antimicrobial Agents and Chemotherapy Second Interscience Conference on, 1053
Antituberculous Drug Ethionamide Identification of a Metabolite of the (P O Kane), 495
Antoni, F , et *al* Nucleic Acid Content of Inflammatory Cells, 704
Aphid Mode of Host Selection by an (R J D Wensler), 830
Aphid, *Myzus persicae* (Sulzer), on a Completely Defined Synthetic Diet Artificial Feeding and Rearing of the (T E Mittler and R H Dadd), 404
Apirion, D A General System for the Automatic Selection of Auxotrophs from Prototrophs and vice versa in Micro-Organisms, 959
Apothecial Stipe of *Sclerotinia sclerotiorum* An Inhibitory Growth Correlation in the (Ruth M Henderson), 826
Apparent Solar Control of the Effective Capacity of a 110-V 170 AH Lead-Acid Storage Battery in an 11-year Cycle (D R Barber), 684
Appearance of Fructose-1,6-Diphosphatase in Post-Natal Rat Liver (F J Ballard and I T Oliver), 498
Appearance of New *N*-Terminal Groups by the Action of Rennin on Casein (P J de Koning and J Stadhouders), 802
Apple Virus Inactivation by Heat Therapy and Tip Propagation (A I Campbell), 520
Apples and its Possible Relationship to Ethylene Biosynthesis Fatty Acid Control of Ethane Production by Sub-cellular Particles from (M Lieberman and L W Mapson), 1016
Appleton, Sir Edward Radio and the Ionosphere, 225
Applied Mathematics F T M Smith appointed lecturer in, 24
Applied Mechanics Courses in (University of Sheffield), 24
Apurinic Acid Non-Antigenicity of Synthetic Polyribonucleotides and (S Yachnin), 1319
Aquatic Mode of Life Adaptations of the Mammalian Skin to the (Dr W Sokolov), 464
Aqueous Dye Solutions Effect of Heat on the *p*H of Water and (Edward Gurr), 1199
Aqueous Non-electrolytes Solution Hydrates of (D N Glew), 698
Aqueous Salt Solutions Influence of Mechanical Agitation on the Nucleation of some (Dr J W Mullin and Dr K D Raven), 35
Aqueous Solutions of Aliphatic Amines Ultrasonic Relaxations in (J F. McKellar and J H Andreae), 778
Aqueous Systems Effect of *p*H on the Radical Yields in the γ-Radiolysis of (F S Dainton and W S Watt), 1294
Arabidopsis thaliana Differential Response to Mutagens in (A D McKelvie), 409
Aragonitic Fossils in the Lower Carboniferous of Scotland (A Hallam and M J O'Hara), 273
Archegoniate Plants The Growth and Development of the Lower, Symposium on (Prof C W Wardlaw), 117
Archer, O K , et *al* Reduced Antibody Response in Thymectomized Rabbits, 191
Arcos, Prof J C , et *al* Kinetics of Mitochondrial Swelling Evidence for Specific Receptor Sites for Inducer Compounds, 1179
Ardran, G M , et *al* Bubbles in Fluidized Beds, 278
Argentina Scientific and Technical Research in, 1158
Arginine in Spiders Detoxications of Aromatic Acids with Glutamic Acid and (J N Smith), 399
Argus, M F , et *al* Kinetics of Mitochondrial Swelling Evidence for Specific Receptor Sites for Inducer Compounds, 1179
Arid Zone Research (Prof L Dudley Stamp), 658
Arnold, Prof A H M Electrical Theory on the Giorgi System, *review*, 931

Effect of Dilution on the Lactic Dehydrogenase Isozyme Pattern obtained in the Starch Gel (Elliot S Vesell), 497
Effect of Dinitrophenol on Active Relaxation of Unstriated Muscle (Inderjit Singh), 83
Effect of Environmental Temperature on Conditioning in the New-born Poikilothermic Rat (D F Caldwell, R Brand and J Werboff), 1314
Effect of Fatty Acids, Ketone Bodies, Diabetes and Starvation on Pyruvate Metabolism in Rat Heart and Diaphragm Muscle (P B Garland, E A Newsholme and P J Randle), 381
Effect of Feeding X-ray Irradiated Coliform Bacilli to Tumour-Bearing Mice (Dr A Compton) 1273
Effect of Glutamine on Intoxication caused by Ethyl Alcohol (Lasse Sammalisto), 185
Effect of Heat on the *p*H of Water and Aqueous Dye Solutions (Edward Gurr) 1199
Effect of Hydrogen Ion on the Rates of Migration of Sodium and Potassium Ions (Simo Salminen), 908
Effect of Magnetic Fields on Tumour Immune Responses in Mice (Dr Leo Gross), 662
Effect of Maternal Isoantibodies on the Quantitative Expression of Two Allelic Genes Controlling γ-Globulin Allotypic Specificities (Dr Sheldon Dray), 677
Effect of 6-Mercaptopurine on Carbohydrate Metabolism of Human Cancer Cells (B J Katchman, R E Zipf and James P F Murphy), 500
Effect of Œstradiol on Phosphorylase Activity of Intrasplenic Ovarian Graft in C57BL Mice (Silvio Bruzzone and Ana Brancatelli), 810
Effect of Ouabain on the Resting Tension and the Rate of Net Entry of Calcium-45 in Isolated Perfused Rabbit Ventricles (A H Briggs and W C Holland), 294
Effect of Oxygen on the Electron Spin Resonance Line-Widths of Amorphous Carbons (J W C Spackman), 764
Effect of *p*H on the Radical Yields in the γ-Radiolysis of Aqueous Systems (F S Dainton and W S Watt), 1294
Effect of Phosphoric Acid on Digitalis Compounds (Joseph Bruton, Robert H Herman and Lloyd E Clayton), 904
Effect of Phytohæmagglutinin on Human Serum and Cell Proteins (Lars Beckman), 582
Effect of Pyridine Nucleotides on the 1-^{14}C-Glucose Utilization of Normal Human Red Blood Cells (Robert H Herman, Jesse Berkowitz, Lloyd E Clayton and Jacques L Sherman, jun), 500
Effect of Pyruvate and Acetoacetate on the Metabolism of Fatty Acids by the Perfused Rat Heart (Robert E Olson), 597
Effect of Radiation on the Electrophoretic Mobility of Ehrlich Ascites Tumour Cells (S Hollingshead and D Thomason), 1217
Effect of Regeneration Blastema Auto-transplantation on Subsequent Regeneration in *Triturus* (*Dienyctylus*) *viridescens* (Maria de Issekutz Wolsky and Linda Fogarty), 621
Effect of 'Rogor' (Dimethoate) and DDT on Cotton Mites in Uganda (W R Ingram), 1224
Effect of Salicylate on Plasma Magnesium-Levels (J S Charnock, R Lockett and B S Hetzel), 295
Effect of Strain and Group Size on the Response of Mice to 'Seconal' Anæsthesia (J H Mackintosh), (194, 1304, June 30), *erratum*, 759
Effect of Strain-Rate on the Tensile-Yield Stresses of Niobium and Tantalum (G A Sargent, P J Sherwood and A A Johnson), 374
Effect of Temperature on Hatching in the Cereal Root Eelworm (John Cotten), 308
Effect of Tobacco Diets on Rodents (J A DiPaolo), 1316
Effect of the Maternal Environment on Strain-Specific Differences in the Ovaries of New-Born Mice (Dr Esther C Jones and Prof P L Krohn), 1064
Effects of Administration of Oxytocin and Prolactin on Nucleic Acids and Phosphoprotein Contents of Mammary Glands in Lactating Rats (K Ôta, A Yokoyama and Y Shinde), 77
Effects of Coconut Milk and Kinetin on the Development of the Protonema and Bud Formation in *Pohlia nutans* (G C Mitra, L P Misra and K N Kaul), 1219
Effects of Corticosteroids on Coagulation of the Blood (Sinasi Ozsoylu, Herbert S Strauss and Louis K Diamond), 1214
Effects of Fibrin Surface on Coagulation of Blood (Gary R Dalin and Jessica H Lewis), 87
Effects of Frontal Cortex Lesions on Object Discrimination Learning by Monkeys (John Oxbury and Lawrence Weiskrantz), 310
Effects of Insulin on Turnover of Carbon-14 in HeLa Cells, (G Melnykovych and P A Miller), 499
Effects of Ionizing Radiation and Peroxides on Hæmocyanin (Jack Schubert and William M Westfall), 1096
Effects of Mammalian Growth Hormone on *Cottus scorpius* Blood (A J Matty), 506
Effects of Nuclear Radiation on Electrical Conductivity of Chromic Oxide (M Nachman and L Cojocaru), 694
Effects of Phencyclidine on the Radiosensitivity of Mice (Lt Col J H Wilkins and J H Barnes), 1172
Effects of Standing on the Protein Extracts of Barley Grain (J Mikola, M Nummi and T-M Enari), 808
Effects on Sensory Nerves of injecting 5-Hydroxytryptamine into the Skin (N M van Gelder), 185
Egg in the Gametophyte of *Pteridium aquilinum* A Membrane Peculiar to the (P R Bell and K Muhlethaler), 198
Egg-Parasite *Trichogramma embryophagum* Htg Host Selection and Number of Eggs per Oviposition in the (H Klomp and B J Teerink), 1020
Egg-White Lysozyme by Ultrasonic Waves and Protective Effect of Amino-Acids Inactivation of (Dr F M Dietrich), 146
Ehrlich Ascites Tumour Cells Effect of Radiation on the Electrophoretic Mobility of (S Hollingshead and D Thomason), 1217
Eisenia foetida (Sav) Free from Infection with Acephaline Gregarines Cultivation of (H B Miles), 921
Elastase Activity in Human Pancreatic Secretions (S Tindel, I J Schneider, D Shapira and D State), 288
Elastic-Plastic Deformation, Creep and Relaxation Transition Theory of (B R Seth), 896
Elasticity of Soap Films an Amendment (J A Kitchener), 1094
Elasticum Dermal Elastin in Actinic Elastosis and Pseudoxanthoma (J G Smith, jun, *et al*), 716
Elastin in Actinic Elastosis and Pseudoxanthoma Elasticum Dermal (J G Smith, jun, *et al*) 716
Elastosis and Pseudoxanthoma Elasticum Dermal Elastin in Actinic (J G Smith, jun, *et al*) 716
Electric Power Direct Conversion of Fission Heat to (P D Dunn *et al*), 65
Electrical and Control Engineering D W McQue appointed instrumentation engineer in the Department of, 24
Electrical Engineering Partnership between Science and (Sir Willis Jackson), 7
Electrical Engineering Prof A D Booth appointed to Chair of, 946
Electrical Self-Stimulation in the Rat Dissociating Reward from Response in (L J Herberg) 628
Electrical Stimulation of Brain Stem Structures in Freely Moving Monkeys Two Opposite Behavioural effects of the (Prof Juhn A Wada and John Wrinch), 252
Electrical Theory on the Giorgi System (P Cornelius), *review* by Prof A H M Arnold, 931
Electrode Phenomena in Magnetohydrodynamic Power Generation (D W George and H K Messerle), 276

Electroencephalogram of the Rat in Anoxia Correlation of Oxidation-Reduction Changes of Intracellular Reduced Pyridine Nucleotide and Changes in (Prof B Chance and Brigitte Schoener), 956
Electromagnetic Radiation Search for an Effect of Magnetic Fields on (S S Hanna *et al*), 791
Electron Density in *Sceptre IV* Interferometric Measurement of (J Dyson *et al*), 1291

Planning Scientific Investment, 839
Plant Cells Connexion between Protein Synthesis and Salt Absorption in (B Jacoby and J F Sutcliffe), 1014
Plant Development Relations between Day-length and Annual Patterns of (A J Cooper), 1218
Plant Growth Stimulative effects of Aluminium on (C Hackett), 471
Plant-Growth Investigations An Evaluation of Controlled-Temperature Environments for (Dr A Joffe), 1043
Plant Phenolics Group and the British Mycological Society Symposium on "Fungi and their Metabolites", 860
Plant Respiration and Microstructure of Plant Cells (Prof W O James), 886
Plant Tissues Freeze-Drying of (R Thaine), 1014
Plant Transpiration by Cetyl Alcohol Reduction of (T F Neales and P E Kriedeman), 1221
Plants Determination of the Quantity of Carbon and Nitrogen in the Rhizosphere of Young (G W Harmsen and G Jager), 1119
Plants to Root-absorbed Chemical Growth Substances applied to Culture Solutions Response of (W D Mitchell and S H Wittwer), 725
Plaque Assay for Herpes Virus A Sensitive and Precise (William C Russell), 1028
Plaskett, Dr L G Catabolism of Doubly Labelled Thyroxine *in vivo*, 961
Plasma Albumin/Globulin Ratio Endocrine Control of the (Cyril Beardwood, Christine Gilbert and Joseph Gillman), 710
Plasma Albumin and Globulin Fractions Regeneration of Prothrombin Activity by (Dr B C Das), 668
Plasma Creatine- and Creatinine-Levels in Sheep (P J Pearce and J S S Inglis), 391
Plasma Erythropoietin on Formate Incorporation into Nucleic Acids *in vitro* Lack of Effect of (P P Dukes and E Goldwasser), 1222
Plasma Magnesium-levels Effect of Salicylate on (J S Charnock et *al*), 295
Plasma Membrane of Sectioned Intestinal Epithelium after Saponin Treatment An Electron Microscopic Demonstration of a Surface Pattern on the (A R Muir), 1023
Plasma Potassium in Men Climatic Variations of (J G Henrotte and P S Krishnaraj), 184
Plasma Proteolytic Enzymes with the Consequent Production of Pharmacologically Active Polypeptides Activation of Endogenous (Margaret MacKay et *al*), 1206
Plasma Prothrombinase (Dr M J Cross), 451
Plasma *p*H and Carbon Dioxide Tension in the Turtle Relationship between Temperature and (Prof Eugene D Robin), 249
Plasma Protein Pattern of the Mouse Developmental Changes in the (E M Pantelouris and Patricia A Hale), 79
Plasma Salicylate Concentration to Urinary Salicylate Excretion-Rate Relationship of (A J Cummings and B K Martin), 1104
Plasma State of Binding of Natural Manganese in Human Cerebrospinal Fluid, Blood and (George C Cotzias and Paul S Papavasiliou), 823
Plastic/Carbon Replication for Electron Microscopy (H J Hulmston), 206
Plastics Institute Election of President for 1962-63, 759
Plastics Institute and Temple Press Award, 127
Platinum (II) Structure of a Carbon-Bonded Acetylacetone Complex of (Dr B N Figgis et *al*), 1278
Platzman, Robert L , and William P Jesse An Isotope Effect in the Probability of Ionizing a Molecule by Energy Transfer from a Metastable Noble Gas Atom, 790
Plauson, R A , and H D Mallory Direct Observation of Detonation in Compressed Nitromethane, 1293
Pleistocene Physical Background of Britain in the (Prof F W Shotton), 881
Plesch, Dr P H Appointed senior lecturer in chemistry, 24
Plessey Co Ltd Appointment of co-ordinator of research and development for the, 24
Plummer, G An Equine Respiratory Virus with Enterovirus Properties, 519
Plutonium Compounds Radiation Self-Damage in (M H Rand et *al*), 567
Plutonium in Man and his Environment (Philip W Krey, Donald Bogen and Eugene French), 263
Pochapsky, T E Measurement of Currents below the Surface at a Location in the Western Equatorial Atlantic, 767
Poe, A J , et *al* Isomerism of Disubstituted Manganese Pentacarbonyl Bromide, 993
Pohlia nutans Effects of Coconut Milk and Kinetin on the Development of the Protonema and Bud Formation in (G C Mitra et *al*), 1219
Poikilothermic Rat Effect of Environmental Temperature on Conditioning in the New-born (D F Caldwell et *al*), 1314
Point Defects in Niobium, Molybdenum and Tantalum (D E Peacock and A A Johnson), 169
Poisons by Gas Chromatography Rapid Screening of Blood Samples for Volatile (A S Curry et *al*), 603
Polar Regions A Particular Geomagnetic Daily Variation (*SqP*) in the Polar Regions on Geomagnetically Quiet Days (Prof T Nagata and S Kokubun), 555
Polarization in the Central Component of Centaurus *A* (R N Bracewell, B F C Cooper and T E Cousins), 1289
Polarized Galactic Radio Emission Faraday Rotation of (R Wielebinski and Dr J R Shakeshaft), 982
Poliomyelitis Importance of Meteorological Factors to the Incidence of (E N Lawrence, *Brit J Prev Soc Med* , 16, 46 , 1962), 125
Poliomyelitis Vaccine (*W H O Technical Report Series*, No 237, 1257
Political and Economic Planning Annual Report 1961-62, 858
Politzer, W M , and L J A Loewenthal Alkaline Phosphatase in Human Eccrine Sweat, 902
Pollard, Ernest C , and Richard B Setlow Molecular Biophysics, *review* by Dr H E Huxley, 633
Pollution Integrated Surface effects of Atmospheric (E N Lawrence), 266
Poly-α-amino-acids containing L-Glutamyl Residues as Substrates for Pepsin (Hava Neumann, Nathan Sharon and Ephraim Katchalski), 1002
Polyacrylamide Gels Disk Electrophoresis of Basic Proteins and Peptides on (R A Reisfeld et *al*), 281
Polyethylene Formation of Unsaturation and Cross-links in the Radiolysis of *n*-Alkanes and (Dr B J Lyons), 690
Polygalacturonase in Fruits Determination of (G E Hobson), 804
Polymer Fractionation Evaluation of Gel-Filtration Media by (M F Vaughan), 801
Polymer Structure and Properties Bradford Institute of Technology, course on, 759
Polymers Liquid-induced Crystallization in (R P Sheldon and P R Blakey), 172
  Optical Properties and Structure of Crazes in Transparent Glassy (R P Kambour), 1299
Polymerization of Transition Metal β-Diketone Chelates (Dr D P Graddon), 891
Polymethacrylic Acid Observation of Trapped Electrons in (M G Ormerod and L G Stoodley), 262
Polymorphism and Sympatric Speciation Disruptive Selection, (J Maynard Smith), 60
Polymyxin B in Isolation of Naturally Infected Tissues Use of Fungizone and (H Schneider et *al*), 396
Polynucleotides and Hg^{II} Separation of the Strands Reversible Reaction of Double-Stranded (S Katz), 997
Polypeptide and Protein Monolayers at Interfaces Conformation of Synthetic (B R Malcolm), 901
Polypeptides Activation of Endogenous Plasma Proteolytic Enzymes with the Consequent Production of Pharmacologically Active (Margaret MacKay et *al*), 1206
Polyribonucleotide-directed Protein Synthesis using an *E coli* Cell-free System (M S Bretscher and M Grunberg-Manago), 283
Polyribonucleotides and Apurinic Acid Non-Antigenicity of Synthetic (S Yachnin), 1319
Polysaccharide Haptens from Urine of Cattle infected with *Mycoplasma mycoides* (R N Gourlay), 99
Poly(triallyl cyanurate) using a Dynamic Mechanical Method Thermal Isomerization of (J K Gillham and A F Lewis), 1199
Polyunsaturated Fatty Acids in *Hevea* Latex Determination of (Ng Tet Soei), 379
Pontecorvo, Prof G Cell Heredity, *review*, 1239
Poole, Prof Granville *Obituary* by Prof E L J Potts, 435

University of Birmingham Annual Report of the Appointments Board for the year ending 31st December, 1961, 1033
University of Bristol New Department of Mental Health, 229
University of Cambridge Election to fellowships, 860
University of Dublin Appointments, 1254
University of Durham Annual Report of the Appointments Board, 1960-61, 1051
University of Durham, et *al* International Symposium "Magnetoplasmadynamic Electrical Power Generation", 233
University of East Anglia Appointments, 650, 1050
University of Edinburgh Appointments of Lecturers, 24, 655
    Formation of a Research Group in Epigenetics, 331
    Grants received by the, 440
University of Ghana Appointments to Professorships, 20
University of Glasgow Appointments Committee Report of the year ended 31st December, 1961, 1033
University of Hull Appointments to chair of psychology, 20
    Chair of Geology, 857
    Postgraduate diploma course, 127
University of Jammu and Kashmir Appointments, 331
University of Keele Appointments, 24, 544
University of Leeds Personal Chair of Biochemistry, 436
University of Liverpool George Herdman chair of geology, 436
University of London Appointments, 1257
    Grant for Nuclear Reactor, 331
    Natural History Certificate Course, 333
University of Minnesota Appointments to Professorships, 20
University of Nottingham Appointments to readerships, 440
University of Oxford Wykeham Professorship in Physics, 860
    Readerships, 860
    Lecturers, 860
University of Queensland Appointments, 651
University of Saskatchewan Chair of Electrical Engineering, 946
    Linear Electron Accelerator, 123
University of St Andrews, 858
University of Sheffield Courses in Applied Mechanics 1962-63, 24
    Appointments, 334, 655
University of Southampton Appointments, 334, 655, 756
University College of Swansea Appointments to Lectureships, 24
University of Utrecht Opening of the Biohistorical Institute of the, 437
University of Western Australia Chair of Soil Science, 858
University of Yale Establishment of a new Department of Biology, 655
University of York Appointments, 650
Unresponsiveness to Unrelated Antigens induced by Paralysing Doses of Bovine Serum Albumin (P Liacopoulos, B N Halpern, F Perramant), 1112
Unstriated Muscle Effect of Dinitrophenol on Active Relaxation of (Inderjit Singh), 83
Unusual Fluctuations of 5577A *OI* Airglow Emission Intensity on October 28-29 1961, (S M Silverman), 481
Upper Air A Working Model illustrating Density of the (H K Paetzold), 1188
Upper Atmosphere Relative Abundance of Lithium Sodium and Potassium in the (H M Sullivan and D N Hunten), 589
Uptake of Glucose, Amino-Acids and Vitamins by Human Amnion Cell Cultures Infected with a Tick-borne Encephalitis Virus (Dr P Halonen, L Hjerp, M Pyhtila and P Weckstrom) 659
Uræmia Role of Carbonyl Chloride in the Production of (D K Sen) , (193, 889, March 3), *erratum*, 655
Uranium Contents of Australites Thorium and (R D Cherry), 1184
Uranium during Alpha/Beta Cycles Under Small Stresses and a Quantitative Interpretation of the Mechanical Weakness of Metals Undergoing Phase Transformations Deformation of (Dr R H Johnson and Dr G W Greenwood), 138
Uranium Production of Enriched, 230
Urban Decay Manchester Joint Research Council Technical Information Centre, *Newsletter*, June 1962, 438
Urea Synthesis in Rats treated with α-D,L-Methylaspartic Acid (F Cedrangolo et *al*), 708
Uridine Diphosphate Glucose-Glycogen Synthetase Activity in the Chick Embryo (T Adesanya Ige Grillo and Kenji Ozone), 902
Urinary Salicylate Excretion-Rate Relationship of Plasma Salicylate Concentration to (A J Cummings and B K Martin), 1104
Urine of Cattle infected with *Mycoplasma mycoides* Polysaccharide Haptens from (R N Gourlay), 99
Urine of the Laying Hen Crystalline Œstrone isolated from (L Ainsworth and R H Common), 77
Urine Excretion of Haptoglobin in Normal (I Berggård and A G Bearn), 1311
Urine Quantitative Evaluation of Human Chorionic Gonadotrophin in Pregnancy (P G Lynch and Herta Schwabacher), 246
Uritani, Ikuzo, et *al* Isolation of Esculetin from Sweet Potato Roots with Black Rot, 726
Uruno, Shinobu, et *al* Acid Leaching of Thorium Carbide, 267
Use of an Integrating Stage for Measurement of Wood (M Kaeiser and S G Boyce), 1917
Use of Di-(2-ethylhexyl) Orthophosphoric Acid for the Separation of the Rare Earths by Reverse Phase Partition Chromatography (T B Pierce and P F Peck), 597
Use of Dihydrofolate Reductase as a Biochemical Index of Chemotherapy (Stewart R Humphreys et *al*), 453
Use of Fungizone and Polymyxin B in Isolation of Naturally Infected Tissues (H Schneider, J R Brown and E E Muirhead), 396
Use of Goose Cells in Hæmagglutination Tests with Louping ill Virus Antigen (H Williams and H Thorburn), 520
Use of Indium Trichloride for the Separation of Native, Denatured and Single-stranded Deoxyribonucleic Acid (William G Aldridge), 284
Use of Mechanical Barriers instead of Guard Rows in Field Experiments (J E Goode and W T B Marchant), 410
Uterus Acid Mucopolysaccharides of the Human (G Loewi and R Consden), 148

VACCINE Against Fowl Plague Disease A New Living (G I-H Mickail), 1231
Vacek, K , et *al* Conductivity of Photographic Emulsions, 895
Vacuum Technique Scientific Foundations of (Saul Dushman, edited by J M Lafferty), second edition, *review* by John Yarwood, 1035
Vacuum Techniques (The Special Use of), Congress on, 546
Valence (Prof C A Coulson), Second edition, *review* by H C Longuet Higgins, 431

PARTNERSHIP BETWEEN SCIENCE, TECHNOLOGY AND THE HUMANITIES

SIR WILLIS JACKSON'S inaugural lecture at the Imperial College of Science and Technology on the partnership between science and electrical engineering (see p. 7 of this issue) is of unusual interest, not merely because of the importance of a number of points he makes but no less because of the way it falls into the pattern of several such recent addresses or papers. Lord Hailsham, for example, has repeatedly emphasized the importance of locating institutes for fundamental research in close relation with universities and the danger otherwise of such institutes stagnating within one or two decades, and in addressing the Parliamentary and Scientific Committee last March he referred specifically to the report of the Zuckerman Committee on the organization and management of research, although without, as does Sir Willis Jackson, considering the mobility of scientists in this connexion. To indicate the extent to which the organization of scientific effort is receiving initial discussion, it should suffice to note Dr. W. R. Brode's review of the growth of science in the United States and its relation to the national science programme which appeared in *The American Scientist* of March, and Prof. C. Holton's penetrating analysis of scientific research and scholarship contributed to the *Journal of the American Academy of Arts and Sciences* (*Daedalus*) for Spring, 1962.

Both these articles, like Sir Willis Jackson's lecture, are concerned with factors which encourage creative work in science and, as might be expected, provide strong support for a good deal of Sir Willis Jackson's argument. In particular, Dr. Brode emphasizes the necessity for an adequate supporting body of technicians if we are to utilize effectively the services of scientists and technologists, and Prof. Holton examines carefully the functioning of the group system and its relation to the rate of scientific advance. Both papers distinguish factors which hinder the conduct and organization of research and should contribute to that clearer public understanding of its nature which is an essential step both in securing adequate financial support as well as the conditions which will attract really competent investigators.

Although Sir Willis gives some fascinating glimpses of the opportunities for research in his chosen field and of the interaction between science and technology, and especially of the way the development of new techniques opens up new fields, the core of his lecture is in his reiteration of conditions which determine effective scientific work. First, however, after stressing the need for full freedom of investigation, he delivers a timely attack on the tendency to disparage technological or applied research. This is quite independent of the appropriate balance between fundamental and applied research. The intellectual or professional effort involved in industrial research and development is in no way intrinsically inferior to that required in research into purely scientific problems; both can on occasion be trivial, but the nature of the problem determines the effort required, and if our colleges of technology, for example, are to gain their rightful place in the educational structure, the value of the applied research which they undertake must be properly recognized.

If Sir Willis had done no more than give this timely rebuke to the attempt to disparage applied research, as such, wherever conducted, his inaugural lecture would have been of real service. He could scarcely have struck a more effective blow in support of the research activity of the engineering schools than he has here done by putting engineering research, and applied research generally, as part of research activity in general, and as an essential element in productive activity. For that attitude to be widely and effectively dissociated, however, much wider mobility of staff will be required and it is in this connexion that Sir Willis welcomes the observations of the Zuckerman Report.

Sir Willis sees clearly that useful as will be some improvement in mobility within the Scientific Civil Service, what is really required is greater mobility in industry and in educational institutions generally. The Zuckerman Report merely displays the possibility of systematically encouraging and deliberately arranging movement of staff, and even so far as the Civil Service is concerned, it must be admitted that Government handling of staff relations has not exactly been designed to discourage suspicions whether a policy of mobility will not be allowed to affect adversely the careers of scientists. The Zuckerman Report was firm on this point, but some assurances may well be required when attempts are made to implement such a policy. Meanwhile, however, it is also to be noted that such a policy of mobility, at least on a part-time basis, offers a reasonable prospect of overcoming the staffing difficulties in some departments of universities or colleges of technology by the use of qualified senior men from industry in readerships or lectureships in applied science or management.

Sir Willis himself lays some stress on exchanges of this kind and suggests that Britain has been somewhat backward compared with other countries. He does not believe that the teaching of technology should be limited to full-time staff but believes that the raising of the level of technological teaching in Great Britain demands a much greater mobility of staff between educational institutions, industry, Government establishments and the public services, and points to the example already set by medicine. Obviously, here again there is no room for the intellectual snobbery which looks down on applied research as inferior to fundamental research.

Sir Willis Jackson has two fields particularly in mind: one is the foundation and teaching of the principles of design, and the other is the interplay of scientific, technical, economic and human considerations in pursuit of new developments and in handling major national and international projects Britain's arrangements, he comments, are much too compartmented, leading to absence of mutual understanding, sympathy and respect, to delays in implementing in one domain what is emerging from another, and to failure to produce enough men capable of rising above particular loyalties to resolve the increasingly complex problems which face the community The great danger is that, at critical points, tradition will delay decisions on policy too long.

Sir Willis is particularly anxious as to the effective co-ordination of the national effort both in research and in production—not so much the existence of duplication of research, development or design effort, as the waste of manpower, particularly trained manpower, through the absence of supporting technicians or craftsmen, inefficient and unimaginative direction, and the lack of appropriate co-operation arrangements While he recognizes that the Government has its own responsibilities, particularly on the educational side and in stimulating the conditions which, for example, through interchangeable pension systems could encourage mobility of staff, he is clear that, quite apart from its bearing on the maintenance of a free society, a major responsibility for initiative must rest with industry itself He too sees the use of civil research and development contracts as providing an important contribution, but insists that the right place for research and development is as close as possible, organizationally and in location, to design and industrial production if the difficulties of transfer are to be kept to a minimum and the maximum use made of industrial experience

It is at this point that Sir Willis refers to the importance of the wise use of skilled manpower and the need not merely to see that the scientist and technologist is fully supported with technicians but also that highly trained men and women are not used carelessly in work for which men and women of lesser qualifications would serve. It is here also that he points out the wide opportunities for inquiry that confront us we have not yet seriously attempted to relate the advance of scientific knowledge and of its technological application to the rate of growth of the Gross National Product. The full authority of this lecture is put behind what Dr. B V. Bowden urged before the British Association last year in regard to the use of the computer and like methods in administration

Even more seriously Sir Willis Jackson is concerned over the neglect of the sociological problems which Britain has encountered It is not simply a matter of education for management in the narrowest sense, of providing industry and Government alike with managers competent to use the new techniques that technological advance has put at our disposal and dealing objectively and factually with complexities which would otherwise be beyond human capacity We are woefully incapable of resolving in a rational way the human problems which have issued from automation, telecommunications and other advances of technology which have created highly complex sociological problems. The scale and pace of effort in the physical sciences are still increasing, and we need a more serious attempt to establish the human sciences in a saner relation to the physical ones

A recent survey by the British Academy has emphasized the wide disparity in support given in Britain to the human and physical sciences Referring to this report, Sir Willis Jackson contrasts the £40,000 awarded by the Department of Scientific and Industrial Research, through its Human Sciences Committee in 1959–60, to the investigation of human problems in industry with the £5·775 million awarded by the Department for the support of research Sir Willis does not press the comparison, which may stand, for the supply of competent investigators is also too limited and one problem is to attract a greatly increased number of able investigators and provide them with experience Meanwhile, however, it is equally important that the minds of the increasing proportion of able recruits attracted to the physical sciences and technology should at least be open to the sociological consequences of their work and that they should be equipped in some measure to discharge the widening human, as well as the scientific and technical, responsibilities which lie ahead of them, and it is refreshing to note that, in concluding his lecture on this note, Sir Willis does not omit to look at the place of our scientists and technologists as agents of a new diplomacy nor hesitate to assert that they will have an increasing part to play as advisers and as teachers in the progress of the under-developed countries, not only carrying conviction in regard to particular scientific and technical expertise but commanding also respect as ambassadors of broad, sympathetic vision, sound judgment and unassailable integrity

This inaugural lecture is one that the Minister for Science will no doubt be prompt to note, and this is as it should be for it argues on lines which Lord Hailsham has often been disposed to argue, and on him must fall some of the responsibility for ensuring that the necessary resources are made available The theme, however, is one that no less concerns the universities, the professional institutions and industry Even on the level of finance all the responsibility cannot be attributed to the Government industry itself must bear a major share, and in regard to research into the human sciences, the universities have some responsibility for finance as well as organization if they expect to avoid the earmarked grant being brought into use Especially perhaps, however, the responsibility rests on the professional institutions, for much must depend not only on their readiness to co-operate with Government departments and institutions, with the universities and the colleges of technology and also with industry, but equally on the outlook and the professional ideal which they set before their members In the end the character of the partnership between science and electrical engineering, or between science and other technology, will depend on the vision and judgment and public spirit which the technologist brings to the service of his profession.

ADHESION AND ADHESIVES

Adhesion

Edited by Prof D D Eley Pp x+290+11 plates (London Oxford University Press, 1961) 55*s* net

THE subject of adhesion, like so many subjects of technical importance, does not fall within the boundaries of any one branch of science, but draws on the activities of chemists, physicists, engineers and others This renders the need for a good systematic text-book both more desirable and more difficult to satisfy If the book is to be anything like comprehensive, it is almost inevitable that it should be a co-operative venture

The book under review, of which Prof Eley is the editor and part author, is the outcome of the discussions of a committee on the subject of adhesion Its outlook is fundamental in the sense that it is concerned primarily with scientific principles rather than with detailed applications The subjects included have been chosen with care so as to cover all the principal lines of development

The introductory chapter, on the fundamentals of adhesive joints (D D Eley and D Tabor), sets out the main phenomena to be examined Chapter 2, 'Molecular Theories of Physical and Chemical Adsorption" (C Kemball), gives an excellent account of the types of molecular forces operating between surfaces of dissimilar materials Chapter 3, "Thermodynamic Adhesion" (D D Eley), and Chapter 4, "Thermodynamics and Imperfections of Solid Surfaces" (W J Dunning), deal with the fundamentals of adsorption phenomena, with particular emphasis on the adsorption of liquids on solids Experimental data on surface free energy, enthalpy and entropy, and their interpretation, are discussed Chapter 5, 'Friction and Adhesion between Metals and Other Solids" (D Tabor), discusses in a very illuminating manner the information which has been obtained on the nature of the actual surfaces of contact in the case of clean metals and metals covered with surface films

These five chapters are concerned with 'adhesion' in general rather than with 'adhesives', and it is only in later chapters that the chemical and physical properties of adhesive materials, which are usually high polymers, are considered Thus in Chapter 6 (by A Baker) the principal types of adhesive materials are classified in relation to the chemical reactions involved in the setting process, and their general fields of application are indicated Chapter 7 (by H Warburton Hall) gives a general account of the mechanical properties of thermosetting polymers, which emphasizes particularly the phenomena of visco-elasticity and fracture, while Chapter 8 (by W C Wake) discusses the closely related subject of the rheology of adhesives, but with more particular emphasis on soft or rubbery materials in which the ability to flow and wet a surface is a primary consideration This leads on to "The Distribution of Stress in Adhesive Joints" (I N Sneddon), which to the engineer will appear as the central and most informative chapter in the book This chapter gives an extremely clear account of the remarkable theoretical and experimental work which has been carried out on the analysis of stresses in joints, and has perhaps a more direct bearing on practical design than any of the earlier chapters After this, a short chapter on the physical testing of adhesives and adhesive joints, which is not free from technical jargon, and the editor's "Concluding Remarks" come rather as an anti-climax

While the presentation is generally clear, there are a few places in which difficulty may be encountered Thus, for example, Plate 1, which shows nothing at all clearly, is without value—at least the position (and form ?) of the solid surface, and the specific atoms in the molecules, should have been indicated On p 123 it is not the 'softness' of the metal (which to me means "low modulus of elasticity") but its low yield stress which is relevant to the argument The formula for the elastic energy of a rubber (p 173) is incorrectly given, the 'strains' should be replaced by 'extension ratios' The argument (p 202) concerning the effect of strain energy on the force required to rupture an adhesive bond fails to define the problem clearly In the same chapter 'Griffiths' is used repeatedly for 'Griffith' On p 207 it is difficult to see how a 'stress concentration' factor can have a value less than unity

These, however, are minor defects Bearing in mind the inherent difficulties of the subject, already referred to, and the inevitable additional difficulties arising from multiple authorship, the book as a whole is successful in achieving its purpose, which is to bring together the most important basic facts and theories of adhesion and related phenomena It is a notable addition to the not too extensive scientific literature on the subject, and it can be confidently recommended The comparatively low price should encourage its purchase by individuals as well as by libraries.

L R G. TRELOAR

BIOLOGY OF MAMMALS

Systematic Dictionary of Mammals of the World

By Dr Maurice Burton Pp 307 (London Museum Press, Ltd , 1962) 35*s* net

FACTUAL information concerning the many genera and species of mammals is scattered through a wide and diverse literature often to be found only in specialized libraries The author of this work, perhaps better known in other fields of natural history, has attempted to remedy this situation and has largely fulfilled his aim of providing a source of easy reference to facts not readily available elsewhere in one book The book, not a dictionary in the alphabetical sense of the word, is a compilation of basic biological information for many of the more important species of mammals, and follows the usual systematic arrangement, with species listed in their appropriate orders, suborders and families Any disadvantage to those unfamiliar with detailed mammalian classification is overcome by the provision of an excellent index The author supplies brief but useful notes on the more important features of the higher systematic categories while presenting the distinguishing characteristics, ecology and life-history of individual species in considerable detail, with statistical and other information wherever possible The text is enlivened throughout with small but attractive scraper-board drawings

It is facile to criticize such a book as this, the more so since varying levels of knowledge of its raw material render inevitable some degree of uneven treatment and for reasons of space much has had to be omitted These features are emphasized by the arrangement of the book at the lower levels of classification with related genera and species or those on which information is lacking listed in conjunction with the more detailed notes on one particular species This is confusing at first sight for example, the entry for the European wild cat is followed by brief details of six other genera of cat, and that for the snowshoe rabbit (*Lepus americanus*) of North America by notes on thirteen other species of African and Asiatic hare Scientific names are occasionally antiquated, such as *Rhachianectes* for *Eschrichtius*, the Californian grey whale, or incorrect, such as *Enhydris* for the more usual *Enhydra*, the sea otter There is no bibliography, the author instead listing some of the more important sources in the preface A few of the drawings lack a caption or other indication of the animal portrayed Small errors which have been overlooked include a cross-reference to the New Guinea water rat, *Parahydromys*, which receives no further mention, *Crossomys* being correctly included, *Talpa europaea* is said to extend to Japan the Japanese mole is *T micrura*, the British water vole (*Arvicola*) does occur in the Scottish Highlands, perhaps through summarizing too zealously, the author implies that the world record African elephant tusk is 11 ft 5½ in in length and weighs 226½ lb In fact, he has combined the length of the longest tusk with the weight of the heaviest

Nevertheless, this book will be invaluable to amateur and professional student alike Its detailed treatment of representatives of the entire class sets it apart from others of its kind, and the author is to be congratulated on his useful and comprehensive summary of the literature J H HILL

DRUGS AND THEIR ACTIONS

Drugs, Medicines and Man

By Prof Harold Burn Pp 232 (London George Allen and Unwin, Ltd , 1962) 25*s* net

THE readers of this useful and clearly written work will be grateful to Prof H Burn for having used his great gifts of exposition in presenting them with an easily understandable account of drugs and their actions This is a subject that deserves such a treatment, not only because of its scientific interest, but also because drugs are of importance to all, patients and users of the National Health Service, and the tax-payers For all these reasons it would probably have been more appropriate to have this book reviewed by one who is not in his daily work concerned with the action of drugs and who is not familiar with many of Prof Burn's ideas and with his contributions to the analysis of drug action However, I myself experience an additional pleasure in reading this book that of meeting old acquaintances in a new setting I realize, also, that there is much for me to learn in this volume One is glad to be reminded of the fact that the attempts to fight disease with the help of the synthetic chemist are of surprisingly recent date In the field of the hypnotics, of the general and local anæsthetics and of the analgesics, the efforts of the chemists can be traced back to the nineteenth century, but many other types of therapy by synthetic drugs, some of the most successful ones, such as the treatment of parasitic and infectious diseases, of hormonal dysfunction of the disorders of the cardiovascular system and of mental illness, are achievements of the twentieth century

Prof Burn describes many instances where the pharmacologist's efforts in the analysis of the effects of drugs on biological processes have guided the work of the synthetic chemist and led to valuable new therapeutic agents However, the book also gives many examples of advances that were the outcome of fortuitous findings The account of some of these accidental discoveries, or the chapter on the doctor–patient–drug relationship, will be readily appreciated and enjoyed by the non-scientific reader Prof Burn also deals at some length with the habit-forming drugs such as alcohol and nicotine One of the attractive features of the book is that he discusses the mode of action of these substances (and of other drugs) but that he does not pass many judgments of value, still, we do learn from him that we should neither eat too much nor take too little exercise, nor disregard the danger of excessive mental strain during our daily work

Anyone who really wants to learn something about the usefulness of drug therapy should read this book, and particularly the last chapter, which gives a brief summary of the achievements of drug therapy For having given the lay reader a clear account of these successes Prof Burn has earned the gratitude of all pharmacologists H BLASCHKO

COMPENDIUMS OF MINERALOGY

Rock-Forming Minerals

By Prof W A Deer, Dr R A Howie and Dr J Zussman Vol 1 Ortho- and Ring-Silicates Pp viii+333 (London Longmans, Green and Co, Ltd , 1962) 95*s* net

WHEN J D Dana, in his early twenties, put together the first edition of his *System of Mineralogy* (published in 1837) he followed the then current fashion and used external characters almost exclusively as a basis of classification, but in the third edition (1850) he rejected the whole of the so-called 'natural history system' and accepted chemical composition as fundamental This feature was retained through the sixth edition (by E S Dana, 1892) which, supplemented by a series of appendixes, remained the standard mineralogy for half a century A chemical classification was followed, too, in the *Handbuch der Mineralogie* by C Hintze In the seventh edition of 'Dana', now in course of publication, a change is being made where feasible to a classification based on crystal structure and chemistry as elucidated by X-rays, a scheme already adopted by A N Winchell in 1933 for the section on silicates in his *Optical Mineralogy*

The volume under review is the first of a series of five which is to treat the restricted field of the rock-forming minerals The first four, on silicates, follow the now customary structural classification, the fifth will describe non-silicates Volume 1 deals with twenty-two mineral groups or species classified as ortho- and ring-silicates The description of a group is prefaced with a brief general account, for each species the ideal chemical formula, the crystallographic and optical data, and the unit cell are listed No data of morphological crystallography are given, drawings of crystals being used only to show the optical orientation of biaxial minerals (in the single case of axinite recourse is had to a stereogram) A description of the atomic structure leads naturally to a discussion of the chemistry in terms of a selection of analyses, to each of which is appended a recalculation showing the structural balance, information from laboratory syntheses is also taken into account A correlation of the optical properties with structure and composition, and a brief mention of diagnostic criteria, are followed by a section on paragenesis This, and the discussions of crystal chemistry, are the specially valuable features of the book Each description is followed by a critical selection of references

The general nature of the production is pleasing Misprints are mainly trivial, in names of localities or titles of papers, but there are several incorrect simple indices in the crystal figures and 'fast' and 'slow' have been interchanged on p ix The distinction of line in the legend to Fig 29 is obscure, and Fig 68 shows decreasing birefringence with an increase in the alkali content of beryl, contrary to the correct statement in the text The minima for refractive indices and birefringence for beryl are inconsistent These, however, are small points of criticism of an important work, the remaining volumes of which will be awaited with interest by all petrologists The great disappointment is the high price, which will clearly place the whole series out of reach of most individuals

F C PHILLIPS

MEN OF PHYSICS

Biography of Physics

By Prof George Gamow (Hutchinson Science Library) Pp x+338+8 plates (London Hutchinson and Co (Publishers), Ltd, 1962) 21*s* net

BOTH as a physicist and as a popularizer of science, Prof Gamow enjoys world-wide esteem His larger works are soundly instructive, and the "Tompkins" books and other lighter contributions are both original and gay It is difficult to assess a book that falls midway between the two categories—and does so intentionally—when one feels that this design is misguided I enjoyed it, of course, as anyone who has lived with physics for many years must, and I can see that in the earlier chapters (where the pace is slower), and in the chapter on relativity (which has appeared before), a layman could learn a great deal, if he got down to close and careful reading My criticism is that the leavening that I find entertaining would distract the uninitiated, particularly in the later chapters There is, for example, a great deal said, in 'much-translated' verse, about an incident involving Niels Bohr and a motor-cycle in Cambridge The version I was brought up on took place in Manchester at the corner of Dickenson Road, involved a No 41 tram and a Dursley-Pedersen push-bike borrowed from an undergraduate named Etchells, a crocodile, and a trolley-boy, but the crocodile (of young ladies from a well-known school in Withington) vouchsafed no comment, and the accurately recorded observations all came from the trolley-boy Legends do get distorted in the telling, and it may be that the author's is the more precise, but will it really mean much to the person who takes the book up in the hope of being introduced to physics ?

There are many excellent features, which can be praised whole-heartedly in any frame of reference The work of Archimedes, of Kepler, and of Galileo is clearly set in perspective in relation to later developments, there is a long discussion of the riches of Newton's *Principia*, which brings out some points that illustrate further the vast range of problems which Newton himself considered The chapters on heat, light, and electricity (with tribute to Faraday and Maxwell in particular, and concise and clear accounts of the contributions of Ampère Oersted and Ohm) are sound, though naturally the pace accelerates Relativity is very well treated, and in the later chapters on modern physics, one is taken behind the scenes to the 'thought experiments' in which Einstein, Heisenberg, and others wrestled with the new concepts that were to revolutionize the world of physics

From the point of view of the scientist who already has some acquaintance with the subject of this biography, indeed, this is a delightful story of the way it has grown up and flourished But, with all respect, the presentation of the lighter side of individual physicists does not seem likely to persuade strangers that physics itself is rewarding to know or to understand, and this is what the author says in the preface he really wants to do

G R NOAKES

LINEAR DIFFERENTIAL OPERATORS

Linear Differential Operators

By Prof Cornelius Lanczos Pp xvi+564 (London D Van Nostrand Co, Ltd, New York D Van Nostrand Company, Inc, 1961) 80*s*

THIS unusual book has many distinctive features, and will be of interest particularly to those mathematicians whose research fields are on the frontier between pure and applied mathematics It emphasizes the close link between analysis, algebra and the theory of numerical processes, and the applications discussed extend into physics and electrical engineering

The first five chapters are concerned with purely mathematical developments, although it is clear throughout that the motivation is the application They cover the theory of interpolation, harmonic analysis, the matrix calculus, function spaces, and the Green's function A chapter on communication problems is given to the theory of the galvanometer the steady-state analysis of music and speech and the transient analysis of noise In another chapter, on Sturm–Liouville problems, the special functions play a large part A chapter on boundary-value problems covers potential theory, vibration and heat flow, and there is a very interesting and unusual discussion of the parasitic spectrum The last chapter deals with the numerical solution of trajectory problems

A notable omission occurs in the lists of references It is surprising that while there are many references to books there is none at all to original papers It would certainly have been proper to refer to some of the many papers on aspects of the book's contents, for example (in §3, 12), on error analysis, ill-conditioned systems of linear equations, and the problem of defining an inverse for a singular matrix

A reference to the author's style may not be out of place In an age where it is fashionable to present mathematics in a condensed form it is a tonic to come across a book written in a style which, while somewhat discursive, is notable for its clarity In places the author would seem to assume scant mathematical knowledge on the part of the reader, but on the whole the book is for the mathematically mature, and the style is such that the message gets across very well, and in a unified fashion The graduate student, about to start reading for research, will find the book particularly attractive

L S GODDARD

Finite Markov Chains

By Prof John G Kemeny and Prof J Laurie Snell (The University Series in Undergraduate Mathematics) Pp viii+210 (Princeton, N J D Van Nostrand Company, Inc , London D Van Nostrand Company, Ltd , 1960) 37*s* 6*d*

THIS book presents an undergraduate course on finite Markov chains by using mathematics no more complicated than elementary matrix algebra. The authors provide a lucid summary in Chapter 1 of the mathematical prerequisites needed so that a conscientious non-mathematician may also make use of the book The theory is developed in Chapters 2–6 and applications are discussed in the final (seventh) chapter Throughout there is adequate use of numerical examples to illustrate the line of the argument The gain in conciseness which results from the ruthless use of matrices is so great that it seems scarcely just to protest that it has not been put to better use However, the following omissions cannot be left unremarked no solutions are given to the exercises given at the end of Chapters 2–6, no comparison is made between the matrix methods used here and other methods of investigating Markov chains, the references given to other work are inadequate This last fault is the most serious, particularly in view of the two audiences to whom the book is addressed Some of the virtues of the book have already been mentioned To these, I would add style and presentation, coherence and, finally, a special commendation for the last chapter which gives a much broader picture of the application of finite Markov chains than the usual questions about queues and cosmic rays ALISON DOIG

Introduction to Space Dynamics

By Prof William Tyrrell Thomson Pp xiv+317 (New York and London John Wiley and Sons, Inc , 1961) 87*s*

ALTHOUGH several specialized books on the dynamics of space vehicles have appeared in recent years, there has been no suitable introductory text-book for university students This deficiency Prof Thomson has now made good He begins with 40 pages on the fundamentals—vectors, kinematics, transformations of axes Then, after a long chapter on particle dynamics and satellite orbits, come discussions of the rotational movements of rigid bodies and the dynamics of gyroscopic instruments Chapter 7 deals with the motions of space vehicles, particularly in rotation, including such topics as the 'de-spinning' of satellites by means of weights flung out on unwinding strings Chapter 8 outlines the methods for optimizing the performance of multi-stage rockets, and the subject of the last chapter is generalized theories of mechanics, as typified by Lagrange's equations The text is generously interspersed with worked examples and problems, which have the virtue of being more realistic than those found in most text-books

The book is sound, well written and easy to follow The topics are, on the whole, well chosen, but, as is inevitable in a book in which the explanations are so full and the examples so numerous, some subjects are dismissed too cursorily (for example, Earth-satellite orbits) and others go unmentioned The omitted topics could with advantage have been outlined, so that students would realize that the book, although an excellent introduction, is an incomplete one

D G KING-HELE

General Microbiology

By Prof William G Walter and Prof Richard H McBee Second edition Pp ix+405 (Princeton, N J D Van Nostrand Company, Inc , London D Van Nostrand Company, Ltd , 1962) 54*s* 6*d*

DESIGNED for use with elementary students, the second edition of this introduction to microbiology needs little commendation The launching seven years ago was quickly followed by three reprintings and now the authors have grasped the opportunity presented by a second issue to make a thorough revision of the whole work

The historical chapter has been omitted, and relevant historical details have been included with the topic under discussion Additional sections deal with lyophilization, the preservation of cultures by freeze-drying techniques, etc In the chapter on the microbiology of foods, the authors discuss preservation by irradiation and the use of food additives The overall production is such that Profs Walter and McBee can fairly claim that they have succeeded not only in providing a well-balanced and scientific introduction to microbiology but also in relating this study of micro-organisms to the everyday life of the student The detailed excellence of the line-drawings shows up the fuzzy inadequacies of many of the photographs T H HAWKINS

Systematic Qualitative Analysis

An Introduction. By Dr. G A Morrison Pp. ix+198 (London Butterworth and Co (Publishers), Ltd , 1961) 25*s*

ALTHOUGH qualitative analysis has a well-established place in school and university courses, there is some difference of opinion as to its relative merits in chemical education It can serve to develop powers of observation and deduction, skill in certain laboratory techniques and practice, and an appreciation of certain physico-chemical principles because it is the study at first-hand of numerous chemical reactions On the other hand, as Dr. Morrison is well aware, analysis can be performed almost entirely "in an automatic way without mental effort"

Systematic Qualitative Analysis is based on the experience of teaching inorganic analysis to first-year university students, and is clearly designed for their use The opening sections offer an outline of the scope of the book, a rather unsatisfactory treatment of dissociation constants, buffered solutions and solubility constants, some descriptions of the usual semi-micro techniques, and details of preliminary tests A section then deals with the semi-quantitative application of solubility product theory to group separations The next section gives details for effecting the separation of cations into groups, and then the analysis of each group is treated fully in separate sections Finally, there are two sections elaborating the analysis and confirmation of anions, an appendix of useful reagents, and a good index

Using Dr Morrison's book it may still be possible to perform analyses in an automatic way However, some mental effort will be needed if only to interpret his 'running nomenclature' This labels each stage of the analysis systematically and quite unambiguously, but its extensive use in the text results in such statements as "If IIBSL^{4}S is Se it should be red, and if IIBSL^{5}S is Te it should be black" (p 113) The book is compact, well bound and presented, but it may seem somewhat expensive at 25*s*

MICHAEL C COX

THE PARTNERSHIP BETWEEN SCIENCE AND ELECTRICAL ENGINEERING*

By Sir WILLIS JACKSON, F R S.

Professor of Electrical Engineering, Imperial College of Science and Technology, London

I DO not think my civil and mechanical engineering colleagues will disagree when I say that electrical engineering differs from their subjects in that it is much younger and had its origins in scientific speculation and experiment rather than in practical achievement Granted that the first practicable electric telegraph was in operation in 1797, the subject of electrical engineering is nevertheless normally, and rightly, regarded as starting from Faraday's discovery of the principle of electromagnetic induction in 1831 Since that date its progress has been continually stimulated, and periodically revitalized, by scientific discovery, notably by discovery in physics But it has at intervals reciprocated by providing science with new techniques and new tools for further scientific investigation, and this interchange and interdependence—this partnership—has been of profound benefit to both

There are, no doubt, many permissible definitions of engineering One, which I myself like, is that it is the economic exploitation by one technique or another of the properties of materials Indeed, when I chose the title of my inaugural address I had in mind devoting the greater part of it to this subject, for it illustrates perhaps best of all the ways in which the work of physicists, chemists, metallurgists and mathematicians has affected, and to a large extent determined, the trends of progress in electrical engineering—how the refinement and utilization of special properties of particular materials has opened up quite new facets of electrical development.

The materials of interest to the electrical engineer are classified as conducting, semi-conducting, insulating, magnetic, structural and nuclear In the full, written version of my address I have summarized some of the most significant recent developments in semi-conducting, insulating and magnetic materials and the engineering consequences of these developments.

I have outlined, for example, how the science of semi-conductors has been transformed during the past 15–20 years from an interesting commentary on an empirical practice in the rectification of alternating current—a commentary which permitted no very useful deductions to be made as to how improved solid-state rectifiers might be manufactured—to a framework of knowledge and understanding providing for the production of devices—notably the transistor—which are predeterminate, more efficient and reliable, and vastly more extensive in scope, than could possibly have resulted merely from practical observation and common-sense improvements With these devices have come new techniques of repetitive manufacture, under conditions of laboratory cleanliness and precision, and a new form of electric circuit engineering

I have given similar illustrations, in respect of insulating and magnetic materials, of the contributions which the scientific disciplines I mentioned have made to the progress of my subject

The story of the impact on electrical engineering of the science and technology of materials is at a fascinating stage New solid-state devices of great scientific ingenuity and carrying baffling names—the Hall effect multiplier, the tunnel diode, the maser, the laser, the cryotron—are appearing with amazing rapidity Their engineering significance is necessarily still largely unestablished, but they herald important further changes in electrical engineering technique Among other prospects, low-temperature physics may soon penetrate not only the domain of computers, but also that of power engineering Scarcely have the manifold materials problems of what is already called the conventional nuclear power station been reasonably resolved, and the prospect of early economic power generation by this means established, but the race is on for other new means of power production—the thermoelectric generator, the thermionic generator, the magnetohydrodynamic generator, the fuel cell and the thermonuclear fusion type reactor—and in each case the production and use of suitable materials in appropriate context are likely to provide the key to success

There is also the parallel story of how, by playing his part in a continuous game of leapfrog, the electrical engineer has helped the scientist through his commercial production of scientific equipment such as the electron microscope, the mass spectrometer, various forms of particle accelerator, and electronic components of increasing reliability, decreasing cost and vanishing size until, for use in satellites, they can be compressed to a density of some 10^8 components per cubic foot

Perhaps I should have been wise to adhere to these comparatively uncontroversial themes In the event, however, my original intentions were overridden by a stronger urge, the desire to discuss a number of factors bearing on the translation of the results of scientific investigation into engineering achievement—factors which I believe give cause for concern and to be in need of more attention, and of action, in Britain than they are perhaps receiving

The factors to which I shall refer do not apply only to electrical engineering, but it is there, of course, that I have mainly observed them Nor do I pretend that they are the only factors In fact, some people may consider that they are not the most important ones I also recognize that they have widely varying relevance in respect of individual organizations and of persons Some may rightly feel, therefore, that what I say has no relationship to themselves, in which case I beg them to bring their influence to bear on situations to which my remarks may be thought more applicable

---

* Substance of Sir Willis Jackson's inaugural address delivered on May 8

First, I want to refer to the pure scientist and his attitude on occasions to engineering and to engineers In a recent lecture Dame Kathleen Lonsdale said "Science is knowledge obtained by observation, by experiment and by subsequent deduction Natural science is the investigation of the nature and properties of natural bodies and of natural phenomena The object of the scientist is the determination of general laws and the deduction of principles from the effects which are observed"

It follows that outstanding scientists, and those who show promise of becoming so, must be free to follow the directions which their scientific curiosity dictates, without concern for the possible engineering significance of the results of their work This freedom has been a well-safeguarded characteristic of university science in Great Britain and I hope it will remain so It can be tampered with only at grave risk to the seed-bed from which important contributions to future progress in engineering will spring It follows also that these scientists must, so far as is practicable, be provided with the most up-to-date facilities and tools of investigation, if they individually—and through them the country—are to remain in the forefront of scientific endeavour and achievement

It is understandable, therefore, that they should be critical of Government—since funds come in increasing proportions from this source—when they consider that the resources being made available to them are inadequate and restricting, and critical of our industry when they consider that it is failing, relative to that of other countries, to translate the results of earlier scientific work speedily enough into the kinds of equipment necessary for their further pursuits

But what I myself do not find understandable is a tendency I have observed among some of these scientists to regard the process of translation of the results of scientific work into engineering achievement as a markedly lower-grade activity than their own, to be unsympathetic to the problems and difficulties which can be associated with it, and to generate in their better students an attitude of mind which is antipathetic to their later participation in it The outcome can only be to retard an improvement in the situation about which they may rightly be constructively critical

Whatever may be the individual view as to how much of available moneys should be spent on research by Government, or by industry within itself, and for what purposes, the fact is that the amount of these available moneys is dependent on the productivity, and in our kind of society on the profitability, of our manufacturing industry in the face of an increasingly competitive situation If this is a case of the hen and the egg, and if the pure scientist and his industrial compatriots appear sometimes to have different views as to which is the egg, I would beg the pure scientist to show a greater willingness than is sometimes apparent to recognize that the conduct of applied research and development in industry, and the speedy translation of its results through design and manufacture into efficient, reliable and economic pieces of engineering equipment, are activities which can make intellectual demands no less severe than, though different from, his own and involve problems of human relationships from which he is largely protected, and that it still lacks in Britain a public prestige at all commensurate with what he himself enjoys

Those who are rightly concerned to increase the research activity of the engineering schools should also be cautious lest their student participants fail to appreciate that research applied to engineering is not a thing apart, but something which to be effective must be woven into the whole fabric of productive activity, and that it demands of the research worker experiences which cannot be gained in divorce from the environment in which this activity is conducted

The training of selected young people in the processes of research is the highest level of teaching—in the engineering no less than in the science schools—and is an essential part of the activity of these schools Its basic aim should be to stimulate inquisitiveness, and develop the powers of satisfying it, in relation to the problems of engineering, and care must be taken that its pursuit does not obscure the fact that the aims of engineering are different from those of science—though the two activities are inextricably interwoven—and that the scope for inquisitiveness in engineering is not restricted to its research domain

If our national weakness lies not in the quality of our research but in our relative inability to translate its results into engineering achievement, it is of limited value for the research worker to criticize from the touch-line an unwillingness—whether this be real or apparent—of the practising engineer to take advantage of his work, and detrimental to give the impression that he regards the work of these engineers as a comparatively straightforward matter with which he himself does not need, or wish, to be associated Where the situation is weak, he adds little strength merely by writing papers and reports What is often needed is a willingness of the research worker to go into the engineering domain for the express purpose of helping to ensure that his results are used effectively To do this he will need more than research ability, and if he succeeds, and in succeeding attains a position of senior responsibility and authority in this, for him, new domain, he will have done much more than correct a previous weakness in it—he will have established for the research laboratory from which he came an enhanced importance and respect, and an assurance of support for it which might otherwise be lacking

In my opinion the problems of staff mobility lie at the root of much of our difficulty in gaining full benefit from our national research effort The most objective discussion of these problems of which I am aware is contained in the report on the *Management and Control of Research and Development*, published in September last In the commentary on the structure of the Scientific Civil Service, the report says

"The principal defects which it reflects are that too many young scientists are committed prematurely to a permanent career in Government research and, second, that those in their forties and fifties have no option but to stay on as research workers (usually at Principal Scientific Officer level) long after they have made their main contribution to research, and in a period of their careers when their experience and ability would be of value if directed to other activities

"Another major criticism levelled at the administration of, and conditions of service in, the Scientific Officer Class by many of those with whom we discussed the staffing arrangements was lack of mobility According to our evidence, this reveals itself in two ways First, there is insufficient movement of research staff between establishments or, indeed, from one line of research to another As a result, Government scientists are deprived of the stimulus of new work, at the same time as they are denied the wider experience necessary for those who ultimately rise to higher positions of responsibility Secondly, there appears to be an absence of any planned arrangements for exchange or secondment of research staff between Government research establishments on one hand, and the universities or industry on the other, or even indeed, with other branches of the Civil Service Because of this, members of the Scientific Civil Service enjoy fewer opportunities than they should of broadening their experience in a way which would be beneficial both to themselves and to the Government"

It is to be hoped that, arising out of the Committee's suggestions, the situation within the Scientific Civil Service will gradually be improved In varying degrees, however, the same sort of criticisms apply to industry and to our educational institutions None has yet given much evidence of a belief that systematically encouraged and deliberately arranged movement of staff between their respective domains would bring benefit to all

There is one aspect of this in which I have a special interest—namely, the further development of postgraduate courses in science and technology It becomes increasingly evident that a substantial proportion of engineering graduates must supplement their undergraduate courses by a fourth year of more advanced specialized study I am one of those who regard it as highly desirable that participation in the latter should be preceded by a period of training and experience in engineering practice partly as a foundation for a reliable choice of specialist field, and also so that the graduate may gain an appreciation of the grounds on which existing practices in his chosen field have emerged and of the directions in which improvement is required I know that many of the university staff members concerned in the development of postgraduate courses hold this view and have been disappointed with the limited response of industry to the steps they have taken, and have concluded that the only means of ensuring participation in these advanced courses is to accept as students men who have just graduated

There are, no doubt, several reasons for this limited response One has been the shortage of scientists and technologists at a time of rapid industrial expansion Another, in respect of which Imperial College has set a better example than most, though, as I see it, there is still scope for improvement, is that many of the courses provided have been essentially departmental in character, have not drawn on the wider resources of the university and have therefore failed to reveal deliberately and adequately enough the interdependences between the sciences and technology to which I referred initially, and to illustrate the kind of teamwork between representatives of the various disciplines now essential to new industrial development A third, and perhaps the fundamental, one is that of lack at sufficiently senior levels of industry of adequate contact with, and knowledge about, what is being attempted There is as yet too great a separation between the two sides

In this respect I believe we have something to learn from other countries in which for limited periods, carefully selected men, whose primary employment is in industry or Government establishments, are given academic status and contribute to advanced teaching work It is to me quite unrealistic to suppose that the teaching of technology at its highest level can be carried out wholly by men who occupy full-time teaching posts, unless these men return to industry—to a responsible position in industry—or a similar environment at appropriate intervals In my opinion the raising of technological teaching in Great Britain to the level required demands a much greater mobility of staff, between educational institutions on one hand, and industry, Government establishments and the public services on the other, than has yet been achieved, and, in supplementation, that carefully selected men should be fully recognized members of both sides, as has long been the case in medicine

It may be that the initiative in this matter will be taken by the colleges of advanced technology, though I hope that the initiative will not be limited to them

In two respects this kind of help is particularly needed—one, to contribute to the formulation and the teaching of the principles of design, an aspect of engineering on which we are sometimes much criticized and which receives little systematic treatment in present postgraduate courses, the other, to portray the interplay of scientific, technical, economic and human considerations in the pursuit of new developments and in the handling of major national and international projects

I would like to see a much more deliberate and extended movement of selected men between the interrelated activities I have mentioned used as a vehicle of staff development Our arrangements are much too compartmented in all sorts of ways, leading to lacks in mutual understanding, sympathy and respect, to delays in implementing in one domain what is emerging from another, and to the inadequate production of men who can lift themselves above particular loyalties to help resolve the increasingly complex problems with which our community is faced Long tradition has built into the various aspects of our national life a great diversity of restraints and inhibitions, the relaxing of which is, of course, full of difficulties and is not free from dangers But the greatest danger is that at critical points of policy decision we shall delay too long, and that the price we shall have paid is higher than we can sustain The most expensive decisions can be those which are not taken

In one such respect the industry of Great Britain seems to me to give cause for considerable anxiety In his presidential address to the Institution of Electrical Engineers in October last, Mr G S C Lucas gave the following figures, taken from the return of Trade Associations in 1958, for the numbers of separate companies designing and manufacturing particular lines of electrical equipment and prime movers power transformers, 19, steam turbines, 11; domestic appliances, 67, switchgear, 50, control gear, 34, small switch and fuse gear, 32, domestic radio and television sets, 60, semi-conductor devices, 26

This subdivision of our industrial effort—and it occurs on a larger scale in some other industries—produces among the larger organizations a considerable multiplication of research, development and design effort directed to the same, or substantially the same, technical objectives, and the possibility that no one of these concerns has the resources either of manpower or finance to launch a really major attack on a new field Among the smaller ones, it means all too often not only an absence of research and development effort within themselves, but also, in varying degrees, an inability to take advantage of the results of work of this kind being done elsewhere—in particular in the research associations specifically on their behalf

Following my participation in a visit to the U S S R in 1955, I included in an article published in the Institution of Electrical Engineers' *Journal* the question "How can we develop a more effective co-ordination of our own national resources without loss of the benefits associated with a free society?"

Since that date there has certainly been a trend towards the creation of larger industrial units, but there has been little self-initiated movement towards the organization of co-operative research and development arrangements within industry itself on subjects of basic and common interest and importance, such as appear to have occurred between otherwise competing continental companies within the European Common Market In consequence, the scientific and technological manpower of the electrical industry is still dispersed to a degree which throws doubt on its ability to compete in large-scale new development with these continental arrangements, let alone with those of the United States and the U S S R—and this notwithstanding that these countries seem unlikely to be any shorter, if as short, of scientists and technologists per unit of population as Britain is The position appears to me to be worse in some, if not most, of our other industries

Different people lay different emphasis on the responsibility which falls to Government, to the Department of Scientific and Industrial Research and the research associations, to the defence and public services and to industry itself, for finding a satisfactory solution to this situation In my opinion there can be no satisfactory solution without considerable initiative by industry, but if it cannot, or will not, do within itself the research and development work necessitated by the national interest, if not indeed for its own survival, this work must necessarily be carried out in national laboratories There is, of course, much work which can best, and some which can only, be done in this way, and this is no doubt likely to increase But the more research and development are separated organizationally and in locality from design and production, the greater are the difficulties, in our society, of effective transfer, and these will be the more serious if the research and development is carried out by staff lacking substantial experience of the manufacturing domain, and if, having been recruited, they are locked up in permanent separation from it An important, if not essential, component in the answer may be the emergence on an extensive scale of civil research and development contracts in industry financed by Government and the public services

There is a further aspect of our utilization of scientific and technological manpower which requires much more attention than it has yet received, namely, the extent to which some of this manpower is performing duties which, with appropriate replanning of its work, might well be undertaken by men or women of lower academic attainment This process of devolution is, of course, a continuous one in any progressive situation, and it is characteristic that the highly qualified persons so relieved move into other fields of creative effort with similar later consequences It demands for its progression, however, the availability of people, themselves well educated and trained but to a different level, on whom the work can be devolved In this connexion I believe that in stressing our shortage of scientists and technologists we have given inadequate recognition to the importance of the supporting contribution, and too little attention to the needs in education and training, of our technicians, men who in the electrical industry perform such duties as supervisors of the manufacture, installation and maintenance of electrical equipment, as inspectors and testers, as draughtsmen and as assistants to professional people in research, development and design departments It may well be that our greater present national shortage is at this level

So far the technician has been provided mainly by the promotion of craftsmen—whose scientific and technical knowledge and understanding have too often been inadequate for the needs of the rapidly changing situation—or from unsuccessful aspirants to professional status Fortunately, it is now widely recognized that he must be prepared much more deliberately for the duties to be performed, and the recent Ministry of Education White Paper entitled *Better Opportunities in Technical Education* did a great service in defining an improved structure of technical college courses for this purpose It is to be hoped that employers, and the trade unions, will take steps to ensure, for it is a joint responsibility that the improved technical college facilities now being provided will be matched by commensurate facilities for practical training I wish I were confident that this will soon occur, but fear that nothing short of radical changes in our systems of apprenticeship, with inevitable legislation, will achieve the desired results

It is gratifying that the Scientific Manpower Committee is now devoting itself to an assessment of the technician situation and to a study of the problems involved in it

The factors, affecting the translation of the results of scientific investigation into engineering achievement, which I have mentioned bear with others on what is referred to as economic growth—nowadays and everywhere a paramount aim of national and international policies

This aim found expression in the recent decision of the Ministerial Council of O.E C D to set as a collective target for the twenty member countries the attainment, during the 1960–70 decade, of a growth in real Gross National Product of 50 per cent

It was also reflected in the following statement taken from the report of a NATO Study Group entitled *Increasing the Effectiveness of Western Science* "A goal of Western nations should be to devote as much of their national income as possible to encourage research and development appropriate to their needs and their interests For basic scientific work we recommend a level of the order of 0 2 per cent of the Gross National Product as a target for all countries For applied research and development the experience of the technically advanced countries indicates that a goal of 2 per cent of Gross National Product is both desirable and achievable"

I do not think there is much risk of giving offence to the authors of such statements in saying that there is nothing very scientific about them The fact is that we have not yet seriously begun the attempt to relate the advance of scientific knowledge and of its technological application to the growth-rate of Gross National Product Some hard thinking needs to be done on the economic aspects of research and development in this sense, and it seems to me that we would be wise to devote a greater proportion of our increasing scientific potential to the doing of it, lest we increase less effectively, and less profitably in the national interest, than we should the great momentum which the pursuit of physical science and its applications has acquired

The economic aspects of this pursuit are not the only ones which call for increasing attention It is a commonplace to say that the achievements of scientists and engineers are producing changes in man's mode of life over an extending range and with increasing speed and directness, and are raising sociological problems of great complexity In my own field I need refer to no more than the consequences of automation and of world-wide telecommunications These, combined with other recent innovations not restricted of course to electrical engineering, have found us woefully incapable of resolving in a rational way the human problems which have issued from them Yet the scale of effort in the physical sciences and in technology is increasing rapidly, and the pace of its impact will do likewise, though its character may change It will bring further material benefit, and indeed this is greatly needed in many places and by many people, and no doubt the human race will devise means of dealing with its other consequences, however uncomfortably, as it has done throughout history

But is it not time a more serious attempt was made to establish the human sciences in a saner relationship to the physical ones? A recent survey by the British Academy has revealed the enormous discrepancy between the support given to the two sides in Britain In the field which concerns me most directly as an engineer, of the £5 775 million allocated by the Department of Scientific and Industrial Research in 1959–60 to the support of research, only £40,000 was awarded through its Human Sciences Committee for the investigation of problems of human relations in industry It may be that this sum was not out of scale with the worth-while research effort available The point is that the subject needs to attract a much increased number of good people, and I believe it would be a good investment for the physical sciences to lose some of its best for this purpose—not in any expectation of early benefits, but because longer-term ones will not come otherwise

Meanwhile, in so far as our plans draw to the physical sciences and to engineering an increasing proportion of the best young people available in our schools, we must at least open their minds to the sociological consequences of their work and ensure that they are properly prepared to fulfil the widening human as well as scientific and technical, responsibilities which lie ahead of them

As matters now stand Great Britain is engaged in a scientific and technological battle with countries that can draw on richer natural resources and can bring larger numbers of trained men to bear on defined objectives It is a battle in which, whether we like and agree with it or not, national prestige is linked with priority of scientific and technological achievement, and where what is achieved in one part of the world—or well outside it—is known everywhere within a few hours Our scientists and technologists have become not only the guardians and guarantors of our national economy, but also the agents of a new diplomacy in which more than an expanding export trade is at stake They will have an increasing part to play as advisors and as teachers in the progress of the under-developed countries, and must not only carry conviction as experts in their particular scientific and technical specialities, but also gain respect as ambassadors of broad, sympathetic, vision, sound judgment and unassailable integrity

THE SNOWY MOUNTAINS SCHEME, AUSTRALIA*

By Sir WILLIAM HUDSON, K.B.E.

Commissioner, Snowy Mountains Hydro-Electric Authority

AUSTRALIA, a continent of about three million square miles and approximately equal in area to the United States of America, carries a population of only some ten million people Nevertheless, owing to its active immigration programme and progressive national development policy, expansion in all fields of industry is proceeding apace This calls for a corresponding augmentation of public services such as roads, transport, water supplies and, last but not least, power

In the field of power production, the growth in demand during recent years has been most marked Superimposed on the load growth brought about by the increase in population there has been an average annual increase of approximately 9 per cent in total energy consumption and approximately 7 per cent in energy consumption per capita

Owing to its geographical position astride the dry latitude band of the southern hemisphere, the limited extent of high mountain ranges and the great distance of its interior from the sea, Australia is the world's driest continent Except in Tasmania and at a few localities along the eastern fringe of the mainland, the scope for hydro-electric development on any large scale is limited On the other hand, New South Wales, Victoria and Queensland, the three States which support 80 per cent of the country's population, have extensive reserves of black and brown coal deposits up to 400 ft in thickness in the case of brown coal and more than 100 ft in the case of black Consequently, coal-burning stations account for about 73 per cent of Australia's total power output Excluding Tasmania, which depends almost entirely on its adequate hydro-electric resources for power, the proportion becomes about 83 per cent

There is no commercial production of nuclear power at present, but developments in Britain and North America are being watched with great interest In Tasmania, hydro-electric resources are likely to provide the most economic form of power develop-

ment for many years to come, and the more highly populated eastern States will continue to utilize their abundant coal reserves and water-power potential, but South Australia and Western Australia are likely to turn to nuclear power stations in the 1970's, dependent on the development of economic plants of the order of 100 MW

Taking advantage of modern improvements in power generation and transmission, New South Wales will be installing 275 MW units and Victoria 200 MW units at new thermal stations now under construction on their coal fields, future plans provide for generators of 350 MW capacity The two States have established a 330-kV transmission system which, when completed, will extend from near the Queensland–New South Wales border in the north to Melbourne at the southern extremity of Victoria, an overall distance of 800 miles

It is perhaps paradoxical that Australia, the world's driest continent, has under construction one of the world's largest hydro-electric projects, the Snowy Mountains Scheme (Fig 1) This Scheme makes a

Fig. 2

major contribution to both irrigation and power development, its principal feature being the diversion to inland irrigation areas of the Snowy River waters which previously traversed already well-watered areas and ran to waste in the Tasman Sea.

The Scheme embraces an area of nearly 3,000 square miles of mountainous country and ranks among the largest individual engineering undertakings ever attempted. It involves the construction of nine major dams and several smaller ones, approximately 100 miles of tunnelling, ten power stations and more than 80 miles of aqueducts high up on the mountain ranges to collect the mountain streams which would otherwise miss the reservoirs and tunnels. On completion the Scheme will provide $2\frac{1}{2}$ million kW. of peak load power and 2 million acre-ft. of water per annum for irrigation. Capital cost will be £320 million sterling. By the sale of electricity at competitive rates the Scheme can meet all costs of power production plus those attributable to the supply of water for irrigation without receiving any revenue for the latter.

Earlier investigations and negotiations eventually led to the agreement between the Commonwealth Government and the Governments of the States of Victoria and New South Wales on the distribution of power and water between the two States. The Scheme's main storage, Lake Eucumbene, has a capacity of 3·8 million acre-ft. (Fig. 3), and this, together with the hydraulic control provided by the complex trans-mountain diversion system, guarantees a high degree of regulation and also flexibility in the operation of hydro plants. Underground construction in the form of long trans-mountain diversion tunnels

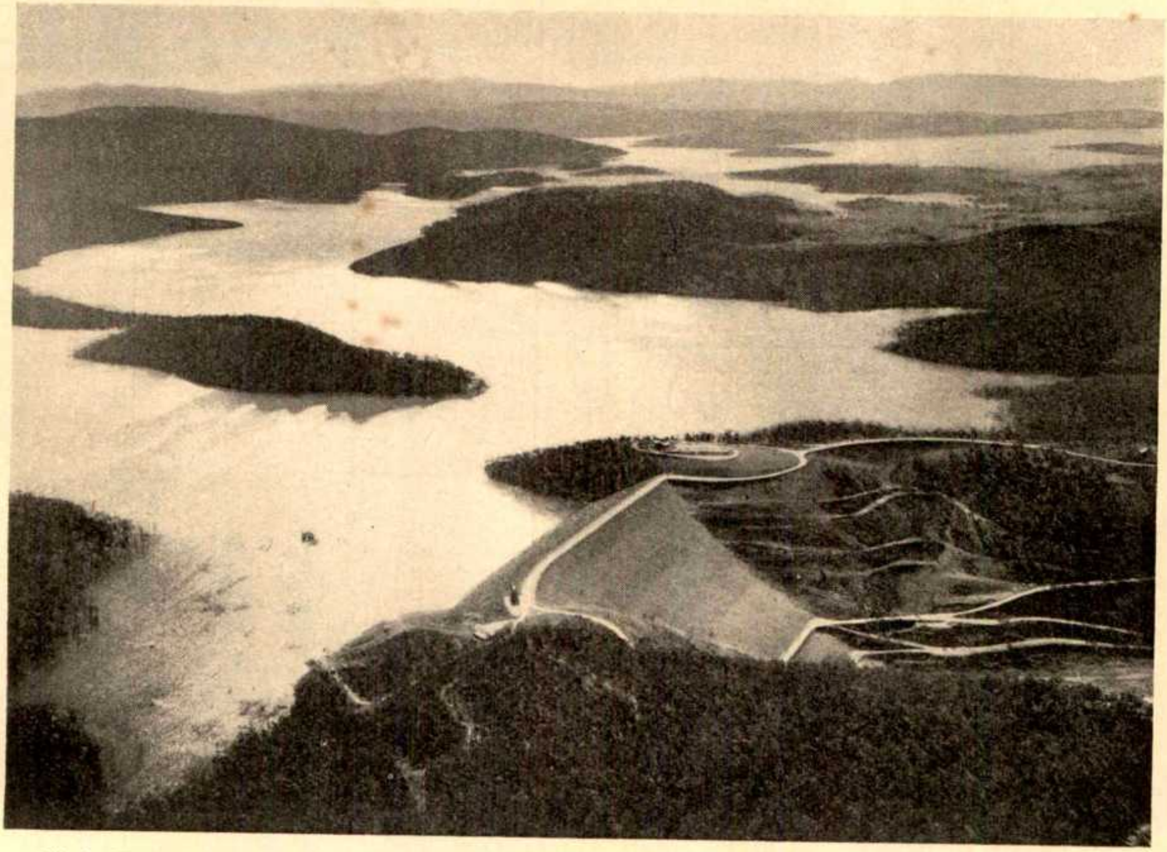

Fig. 3. The 380-ft.-high earth and rock fill Eucumbene Dam forms the Snowy Scheme's main storage, Lake Eucumbene. Part of the vast 3,800,000 acre-ft. storage capacity Lake can be seen in this aerial view

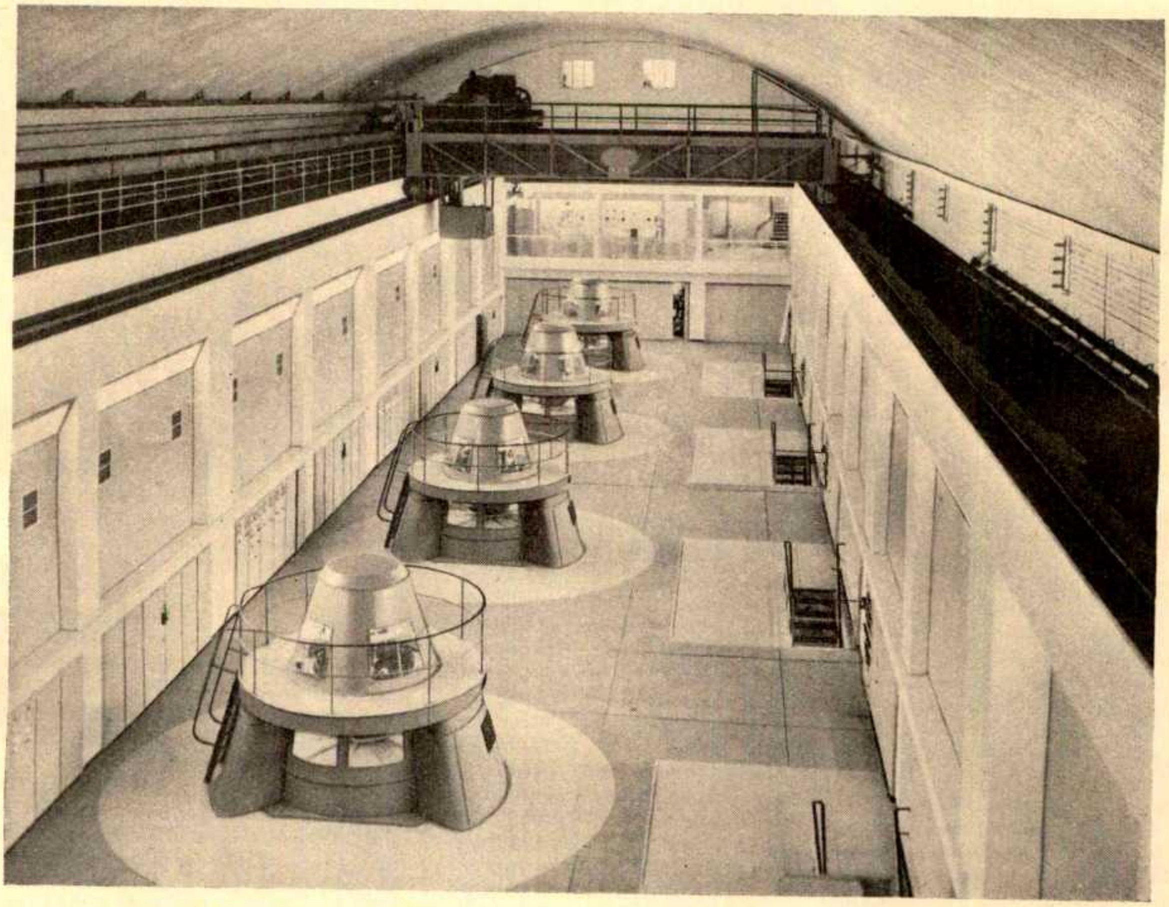

Fig. 4. Tumut I Power Station has an installed capacity of 320,000 kW., and is situated more than 1,000 ft. underground. It has been in service since October 1959

and underground power stations is a characteristic of the Scheme.

The layout of the Scheme falls under two geographical groupings, the Snowy–Tumut Development and the Snowy–Murray Development (Fig. 2).

The Snowy–Tumut Development centres on the diversion of the Eucumbene River, a tributary of the Snowy River, from Lake Eucumbene through a trans-mountain tunnel to Tumut Pond Reservoir on the Tumut River, a tributary of the Murrumbidgee. Storages are also provided on the Upper Murrumbidgee and Tooma Rivers and diversion tunnels bring the waters of these rivers into the Tumut Pond Reservoir. From there, the combined flows of all four rivers will pass through four power stations spaced along the Tumut Gorge, to Blowering Reservoir, where the water discharged from the power projects during the winter months will be held for release during the summer, as and when required, for irrigation in the Murrumbidgee Valley. By utilizing the 2,700-ft. fall from Tumut Pond Reservoir to Blowering Reservoir, the four power stations in the Tumut Gorge will have a total generating capacity of more than 1,000,000 kW. On completion of Blowering Reservoir, the total gain of water for irrigation to the Murrumbidgee River will be approximately 1,120,000 acre-ft. per annum.

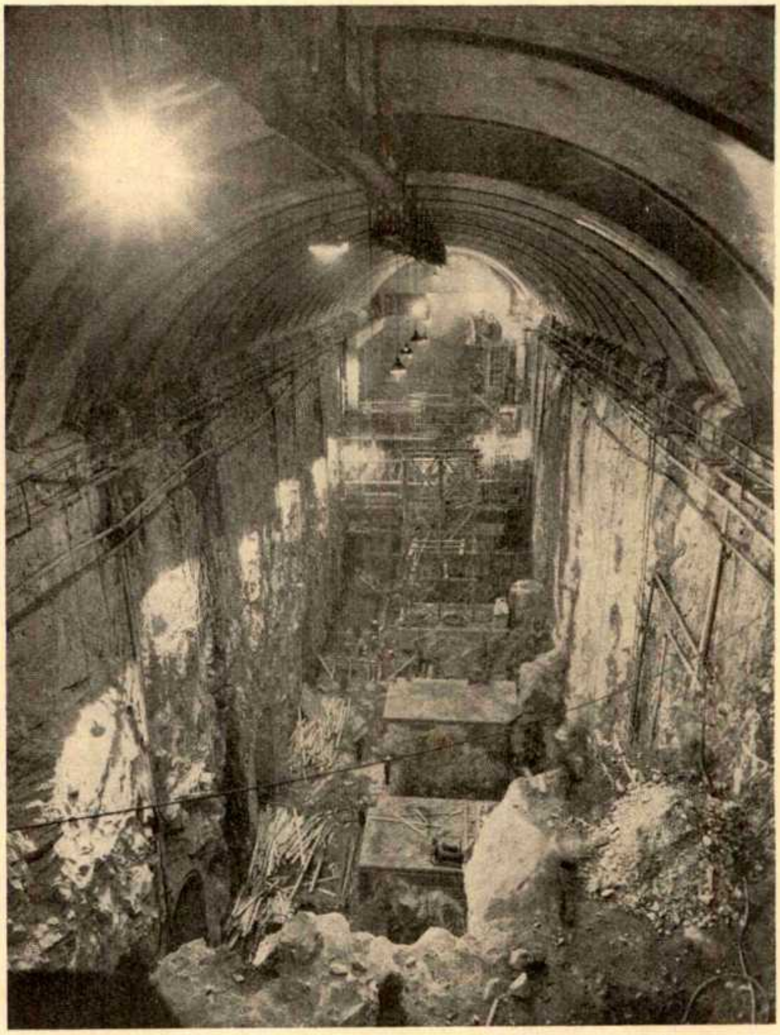

Fig. 5. The 280,000-kW. Tumut II Power Station during construction. The Station is situated more than 800 ft. underground, and this view shows the excavation for the main chamber, which measures 320 ft. long, 51 ft. wide and 105 ft. deep

Of the three completed power stations, Tumut I (Fig. 4), Tumut II (Fig. 5) and Guthega, two are located about 1,000 ft. underground and much use was made of rock bolts which the Authority adopt extensively for rock support in underground workings, eliminating the need in many situations of steel supports and concrete lining.

The Snowy–Murray Development involves the diversion of the Snowy River on the eastern side of the mountains by a dam at Island Bend and a trans-mountain tunnel system, more than 30 miles in length, to the Murray Valley on the western side of the mountains. This tunnel system includes a two-way flow connexion 15 miles long between Island Bend Reservoir on the Snowy River and Lake Eucumbene. Flowing through the tunnels, shafts and pipeline, the diverted waters will fall 2,600-ft. to generate 1·2 million kW. of power in two large power stations. The total gain to the Murray River of water for irrigation will be approximately 800,000 acre-ft. per annum.

The run-off of the portion of the Snowy catchment downstream of Island Bend will be impounded in Jindabyne Reservoir at the point where the Snowy leaves the mountains. A pumping station using off-peak energy will pump water from this reservoir through a tunnel and pipeline 6 miles in length to the trans-mountain tunnel system. The amount of energy required for pumping against a head of 800 ft. to lift the water to the level of the Geehi Reservoir will be about two-fifths of the more valuable 'peak load' energy generated in the turbines of Murray I and Murray II Power Stations by the same water falling 2,600 ft.

Construction of the various components of the development up to and including Murray I Power Station is now proceeding, and plans for the Murray II Project are well advanced. The 760,000-kW. Murray I Power Station will be the largest in the Scheme and, at the time of ordering, the Francis type turbines (160,000 b.h.p. at maximum net head of 1,710 ft.) represented a unique combination of high head and large output for this type of machine. Twin pipelines, a mile long and approximately 13 ft. in diameter, supplying this station will involve 10,000 tons of steel, of which a large part will be high-tensile, notch-ductile grade.

Many problems have been met in establishing in a remote and mountainous area an organization to carry out the work; for example, the need to provide several townships, including housing, schools and modern amenities for the works forces, and measures to encourage speed of construction. A feature of the work so far carried out has been the increasing rate of progress achieved, particularly in hard-rock tunnelling where maximum advancement per face represented substantial increases on the world record tunnelling speeds current at the commencement of the Scheme. Also notable is the almost complete absence of industrial trouble during the past twelve years.

Two out of every three persons comprising the working forces are 'New Australians', recent arrivals from Europe who have chosen Australia as their future homeland. More than 30 countries are represented. The integration of these men and their families, many of whom on arrival could not speak English, into an Australian community proved to be an interesting and successful experience.

[After describing the Authority's Engineering Laboratories and the work of survey, diamond drilling and hydrology teams as examples of the thorough investigations carried out before and during construction, Sir William closed his address with a reference to the indirect but nevertheless substantial benefits arising from the Scheme.] The construction of an extensive road system has greatly facilitated public access to one of the most attractive winter and summer recreation areas in the country, and the Authority's policy is to encourage and assist people wishing to visit the Scheme, 60,000 visitors having been accommodated, fed and transported on two-, three- and four-day conducted tours over the projects in 1961.

The Scheme has now reached the half-way mark. Approximately 300 miles of mountain roads, 50 miles of tunnels, 6 dams, 30 miles of aqueducts have been constructed, and three power projects are in operation supplying water to irrigate dry inland areas and peak load power to the interconnected power systems of south-eastern Australia.

CONTINUOUS PROCESSES BEING INVESTIGATED IN AUSTRALIAN STEEL INDUSTRY RESEARCH

By Dr. HOWARD K. WORNER

Director of Research, The Broken Hill Proprietary Co., Ltd., New South Wales

PRACTICALLY every steel-making plant in the world has greatly increased its output in recent years. Some of this increase has resulted from improvements in technique and efficiency of operation, but in other cases it has been mainly due to the building of more or bigger ovens, furnaces and rolling mills. The high cost of major steelworks units is a matter of serious concern and is leading to re-appraisals of long-established practices like coke-making in by-product ovens, blast furnace iron production, and open hearth steel-making.

It has seemed to me that one way to arrest the trend to bigger and bigger furnaces, ladles, cranes and locomotives in steelworks is to follow the lead of petroleum refiners and chemical manufacturers generally, in replacing batchwise processes, often widely separated, with closely integrated continuous unit operations, and to use, wherever possible, launders pipes and belts to transport materials.

It is appreciated that the handling of molten steel presents difficulties which are not encountered in the transport of oil or plastics, but it is felt that advances in knowledge, the advent of new materials and improved systems of measurement and control have brought the goal within the realms of practical realization.

There are those, of course, who hold that the best coke and steel can only be made batchwise, and with ample time for 'conditioning'. I contend that this is a mistaken view and one which, if maintained, will retard the advancement of the iron and steel industry into the era of full and effective utilization of computer controls.

It is of interest that the trend in this direction has begun at the two ends of steelworks operations; blast furnace ferruginous burdens are now frequently prepared in continuous sintering or pelletizing units, and at the steel finishing end, strip rolling, electro-galvanizing and electro-tinning have become highly automated continuous operations.

An announcement[1] was made in May 1961 at the annual conference of the Australian Institute of Metals that work had started on continuous steel-making[2] in the research laboratories of the Broken Hill Proprietary Co., Ltd. Further information on this and other projects was given[3] at the symposium held at the BHP Central Research Laboratories in March 1962 to celebrate the fifth anniversary of their opening (Fig. 1).

Research on continuous steelmaking has so far been concerned with an appraisal of metallurgical features and with the obtaining of data for the design of a small production unit. It has already been demonstrated in furnaces up to 5 tons per hr. capacity that by the method of continuous 'staged' lancing with oxygen it is possible to produce a wide range of grades of steel; all that is necessary to change grade is to alter the oxygen metered through the last lance, or alternatively to modify the metal flow-rate. Adequate heat is generated in the refining process; increases in temperature of up to 500 deg. C. have been measured along the bath and low carbon steel has been tapped from the experimental units with a superheat of 200 deg. C. The indications are that in full-scale production units there should be appreciable potential for scrap consumption and/or for incorporation of ore, which incidentally need not be in the form of hard lumps as required by the open-hearth process. High magnesium oxide refractories have stood up well to the conditions in the small experimental furnaces; they do not suffer the temperature cycling which is so prone to cause spalling in furnaces operated batchwise.

In certain experiments designed to test the refining potential, remarkable lowering of phosphorus and sulphur contents has been achieved. An intriguing new field of slag-metal chemistry has been opened up, particularly with a practice in which slag can flow countercurrent to metal. The gases, which, of course, are emitted continuously, are both very hot and rich

Fig. 1. Broken Hill Proprietary Co., Ltd., Central Research Laboratories, set among tall eucalyptus trees at Shortland, New South Wales

in carbon monoxide. They would therefore be suitable for use in scrap pre-heating even pre-melting. They could also be used for ore pre-reduction or limestone calcination or for steam raising.

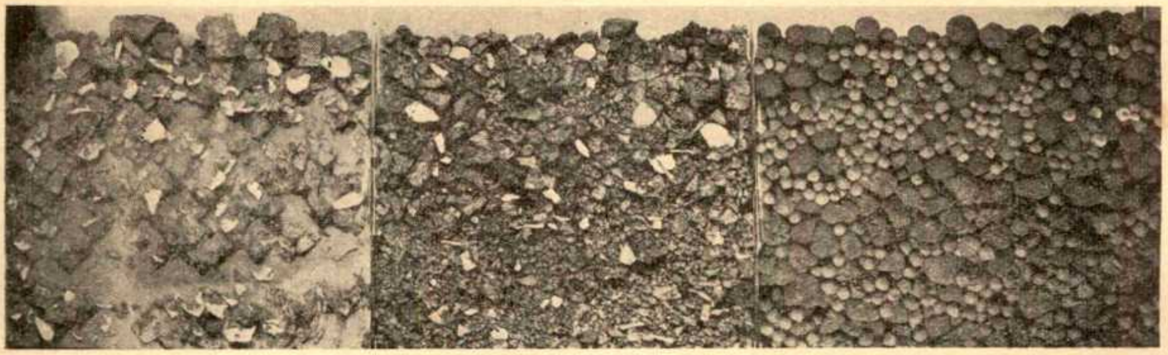
The demonstration of the metallurgical feasibility of continuous steel-making presents a challenge not only to push on with the engineering of full-scale plant but also with: (*a*) the evolution of means of continuous analysis of steel in a slowly flowing stream; and (*b*) continuous or near continuous tapping of blast furnaces. For the former, both physical and chemical methods are being investigated. The solution to the latter will probably lie in two-tap hole practice, hot metal flowing in turn from each tap-hole.

In a production plant it would be necessary to interpose a form of tilting 'mixer' between the blast furnace and the continuous steel-maker and a somewhat similar holding furnace for the steel ahead of casting. The indications are that continuous oxygen steel-making can achieve a steady flow of metal at practically constant temperature, and this is, of course, greatly to be desired in feed to a continuous casting plant. Many troubles arise in present continuous casting plants from changes in temperature in the steel delivered from individual ladles. Finishing additions, preferably in a finely divided form, are appropriately made to the steel as it flows into the tilting holding vessel.

As already implied, future work will seek to achieve not only high metallurgical efficiency in steel-making but also economy in materials handling and site utilization by making the maximum use of gravity flow of liquid metals in hooded refractory launders.

The high productivity of oxygen steel-making processes, whether batchwise or continuous, is possible because of the extremely high rates at which the metalloids, silicon, carbon and phosphorus, burn out of the molten iron when it is jetted with elemental oxygen. This fact has helped the blast furnace to stave off challenges by direct reduction processes. Most of the latter are not able, as is the blast furnace, to produce hot metal with 'internal fuels' ready for oxygen refining.

Contributing materially to the recent great increases in the productivity of iron blast furnaces has been the replacement of ore burdens with either sinter or pellets. The latter, being uniform in size and shape, are showing up to particular advantage



a *b* *c*

Fig. 2. Simulated blast furnace burdens: *a*, unscreened ore, coke and limestone; *b*, screened coke, limestone and fine sinter; *c*, fluxed ore pellets and coke pellets which have by far the greatest permeability to gases

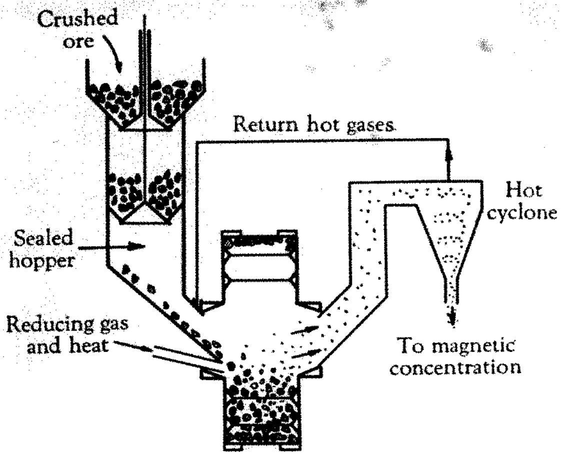


Fig. 3. Diagrammatic section of the pilot plant being used to evaluate simultaneous autogenous grinding and reduction of siliceous ores such as jaspilite

in the relatively few furnaces to which they have so far been charged. It has seemed to the research workers here that if ore pellets can confer such benefits to furnace 'driving-rate', primarily because of their contribution to uniform stack permeability, there should be a further gain if the coke also be added in rounded forms. As yet the researches in this field have not advanced beyond the point of small-scale melting trials in cupolas, but the technical feasibility of producing strong, fissure-free coke pellets or briquettes and of burning them in shaft furnaces has been demonstrated. Significantly, this development has evolved from a systematic study of different methods of continuous coking, and on inferior coking coals at that[4,5]. It has been found that the efficiency of continuous coking can be increased by feeding the coal to the coking unit (strands, columns and kilns are being evaluated) either in the form of pellets or as rounded briquettes.

Not content with the making of strong coke pellets, current research here is concerned with the production of composite pellets in which fine ore, and possibly some flux, are also incorporated. By controlling the heating-rates and with appropriate gas circulation, a substantial degree of ore reduction can be achieved simultaneously with coking. It is felt that the perfection of this practice could contribute to even greater productivity of blast furnaces which are already very efficient 'reactors'.

Investigations of a possible new method of treating siliceous ores have stemmed from a fundamental study[6,7] of the phenomena which occur in a fine-grained hæmatite–quartzite (jaspilite) on heating to about 600° C. in lean combustible gases. Severe intercrystalline cracking occurs due to: (1) the thermal gradients built up in the ore lumps; (2) marked changes in volume in the hæmatite grains as they are reduced to magnetite; (3) the considerable dilation of quartz as it undergoes the $\alpha \rightarrow \beta$ inversion at about 570° C.

The process[8] has been tentatively designated 'CRAG' because it achieves in one unit Combined Reduction and Autogenous Grinding. Experiments in a small pilot plant with 4-ft. diameter grinding drum have yielded very promising results and data are being collected for the design of a large pilot plant.

A new type of dry magnetic separator[9] suitable for recovering the fine magnetite (minus 200 mesh) from the product blown out of the mill is also being developed in the Broken Hill Proprietary Central Research Laboratories.

Thanks are due to the Directors of the Broken Hill Proprietary Co., Ltd., for permission to publish this article and for their continued support of the researches described. Responsibility for the opinions expressed is, of course, accepted by me.

THE INDIAN BOTANIC GARDEN, SIBPUR, CALCUTTA

By Dr. J. SEN

Superintendent

THE Indian Botanic Garden celebrated its 175th anniversary on July 6. The Garden, with its famous great banyan tree, is perhaps the largest of its kind in Asia and occupies an area of 273 acres on the west bank of the River Hooghly. It is situated in Sibpur only a few miles from Calcutta, and, in the words of the late Sir Arthur Hill, a director of the Royal Botanic Gardens, Kew, "offer[s] an interesting and remarkable parallel to those other Royal gardens . . . at Kew, since Kew is only a few miles from London; while . . . Sibpur gardens are within easy distance of the second city of the Empire and are situated on the banks of the Hooghly which washes the shores of Calcutta. Both . . . gardens suffer somewhat from being on the flat alluvial soil of the riverside; the skill of the gardener, however, has transformed both sites into gardens of high scientific interest as well as of great aesthetic beauty, so that they serve as a source of inspiration, education and research for their many visitors".

For nearly two centuries now, Sibpur Garden has been a centre of botanical and horticultural research. Some of the pioneer works on the flora of India, Burma and Malaya, as also the introduction of plants like tea, cinchona, mahogany, etc., to India are credited to men who have worked here. The utilization of jute, improvement of Indian cotton and cultivation of flax, hemp, ramie, tobacco, vanilla, coffee (Arabian and Liberian), cocoa, ipecacuanha, india-rubber, tapioca, cardamoms, potato, henbane, aloes. sarsaparilla, jalap, Japanese mulberry, varieties of sugar-cane and plants of varied economic importance were also made possible in this Garden and through its agency. Since the 150th anniversary about seventy-five plants were successfully introduced in spite of the fact that the Plant Introduction Office in Delhi has already taken over this work. It is needless to discuss in detail the numerous experiments in the cultivation of economic plants which have been conducted in the Garden since its beginning. As regards horticulture, it may suffice to say that a large proportion of the kinds of exotic plants now found in different gardens in India was introduced into the country through the efforts of the Garden authorities, and that the present improved methods of cultivation were to a great extent initiated here. Thus this Garden has played an important part in the economic growth of India.

The present plant population of the Garden is more than 12,000, grouped on a geographical basis (that is, typical plants of a country are planted in a particular area). Among the interesting show-spots in the Garden are the large palm-house, the small palm-house, the orchid-house, the fernery, the cacti and succulents, the branching palms, the screw-pine collection, the bamboo collection, the giant water-lily of the Amazon, the picturesque vistas, and some of the pleasant lakes and delightful walks. The Garden is celebrated as the most useful and the most beautiful in the East, as in the words of the late Sir Joseph Hooker, another director of the Royal Botanic Gardens, Kew, it having "contributed more useful and ornamental tropical plants to the public and private gardens of the world than any other establishment before or since".

The herbarium and library have gradually developed as necessary adjuncts to the Garden. The herbarium was established by Dr. William Roxburgh in 1793, and now contains more than 2.5 million specimens. Since April 1957, the major part of the collection was transferred to the newly re-organized Botanical Survey of India. The library has a valuable collection of about 30,000 volumes on botany, forestry, agriculture, entomology, geology and related sciences. Some old manuscripts, scientific correspondences and albums containing original paintings of Indian plants, which have been and are still being prepared since the early nineteenth century, are part of its rich heritage.

The Lloyd Botanic Garden, Darjeeling, has been developed as a subsidiary garden to the Sibpur Garden. Established in 1878 when Dr. T. Anderson was the superintendent, the Garden in Darjeeling has been the centre of introduction and cultivation of temperate plants, which do not grow in Sibpur. The herbarium contains about 30,000 specimens covering nearly all the species of the Eastern Himalayas. There are a small library and a laboratory.

Thus the Indian Botanic Garden has become an important venue for the botanists in India. They, and often the Indian people, owe a great debt to its founder, Lieut.-Colonel Robert Kyd, and the long chain of his successors, who gave India important economic plants to increase her wealth, and laid the foundation of Indian botany. Dr. William Roxburgh (1793–1814), who was the immediate successor of Colonel Kyd, is rightly called the 'father of Indian botany' for his *Hortus Bengalensis*, *Flora Indica* and *Plantae Coromandelianae* in three large volumes. Some of his original specimens are still preserved in the herbarium. Dr. Roxburgh established jute in this Garden and exported the first 100 tons of this crop to the European market. He was succeeded by Dr. Francis Buchanan (afterwards Sir Buchanan Hamilton) (1814–16), a naturalist of great reputation.

In 1817, Dr. Nathaniel Wallich succeeded Dr. Buchanan. Dr. Wallich organized expeditions into the remote and then little-known regions of Kumaon, Nepal, Sylhet, Tenasserim, Penang and Singapore; in fact, undertook a botanical survey of a large part of the Indian sub-continent, and made extensive collections, which together with other collections were distributed among the herbaria of Europe. His *Plantae Asiaticae Rariores* in three superb volumes illustrated by coloured figures are of a high degree of excellence. He retired in 1846 and died in 1854. When Dr. William Griffith (1842–44) officiated during the lengthened absence of Dr. Wallich in Europe, he was upset to find the denuded condition of the herbarium. His extensive notes and drawings were published in nine volumes after his premature death. Dr. Hugh Falconer, well known for his researches on the Siwalik fossil mammals, succeeded Dr. Wallich and remained in office until 1855. Dr. Thomas Thomson came into office in the same year and retired in 1861. He is well known as the coadjutor of Sir Joseph Hooker in the collection and distribution of an extensive herbarium of East Indian plants, and the joint author of the first volume of a new *Flora Indica*.

Dr. Thomson was succeeded by Dr. Thomas Anderson, who died prematurely in 1870 of a disease contracted during his efforts to introduce the quinine-yielding cinchona plants into the Sikkim Himalayas. Dr. Anderson was also at the same time the first conservator of forests for Bengal and officer-in-charge of the introduction and cultivation of cinchona in India. Mr. C. B. Clarke officiated as superintendent for about two years (1869–71) and was one of the collaborators in Hooker's *Flora of British India*. When Dr. (afterwards Sir) George King became superintendent in 1871, the Garden was still suffering from the effects of devastation caused by the two great cyclones of 1864 and 1867. Besides reorganizing and reviving the Garden and the Herbarium, Dr. King initiated the publication of the *Annals of the Royal Botanic Garden* and himself contributed a number of important papers and monographs to the *Annals*. He was largely responsible for the establishment of the Botanical Survey of India in 1890 and became its *ex-officio* director, and this arrangement of superintendent holding the office of director of the Survey continued until the post of director was abolished about twenty-five years ago.

Surgeon-Major (afterwards Sir) David Prain succeeded Sir George King in 1897 and gained a world-wide reputation by his works on the genera *Pedicularis* and *Dioscorea*, and regional floras. He retired in 1906. Captain (afterwards Colonel) A. T. Gage succeeded him and continued in office for about seventeen years. His works on Euphorbiaceae and the Burmese flora have earned for him a good reputation. Mr. C. C. Calder, well known for his works on *Oxalis* and vegetation patterns of India, took office in 1923. He was succeeded by Dr. K. P. Biswas (1937–55), followed by Dr. D. Chatterjee (1955–60), both well known to Indian botanists. Among the important personalities who at one time officiated as superintendent are Dr. William Carey (1813–14), Sir William Wright Smith (1908), and Dr. J. M. Cowan (1926–27).

This is a brief record of the almost uninterrupted history of the Indian Botanic Garden, which has been thriving under the Government in Calcutta.

NEWS and VIEWS

Ipatieff Prize of the American Chemical Society
Prof. C. Kemball

The Ipatieff Prize for 1962 of the American Chemical Society has been awarded to Prof. C. Kemball, professor of chemistry in the Queen's University of Belfast. The prize, consisting of 3,000 dollars, is named after V. N. Ipatieff (1867–1952) and is awarded once every three years for outstanding chemical experimental work in the field of catalysis or high pressure to a person not over forty years of age. The rules of eligibility state that preference shall be given to American chemists, and the award for 1962, although it is the sixth in the series, is the first to have been made to a non-American. Prof. Kemball has developed a research school at Belfast in the field of heterogeneous catalysis which is acquiring an international reputation. He received a Meldola Medal for 1951 on the recommendation of the Royal Institute of Chemistry and the Corday-Morgan Medal of the Chemical Society for 1958.

Shewhart Medallist of the American Society for Quality Control:
Mr. L. H. C. Tippett

The Shewhart Medal of the American Society for Quality Control "for outstanding leadership in the field of modern quality control" has been awarded to Mr. L. H. C. Tippett, an assistant director of the Cotton, Silk and Man-made Fibres Research Association, Shirley Institute, Manchester. This is the first time that the award has been made to a non-American. Mr. Tippett, who has been at the Shirley Institute since 1925, is the author of many books and papers on applied statistics and quality control and is a leader in the field of statistical investigation of process operations in the textile industry. Earlier recognitions of his work include the Guy Medal in Silver of the Royal Statistical Society and the Warner Medal of the Textile Institute. He was the first chairman of the Committee on Statistics in Industry and Technology of the International Standards Organization during 1949–58, and the first chairman of the Textile Institute's Quality Control Group during 1959–61.

Physics at Minnesota
Prof. C. J. Waddington

Dr. C. J. Waddington has been appointed an associate professor of physics in the University of Minnesota. Dr. Waddington was an undergraduate in the University of Bristol, and afterwards became a research student there, taking his Ph.D. in 1955, after making investigations on the helium nuclei present in the primary cosmic radiation. These experiments showed that the conventional theories of geomagnetism were unable to predict precisely the behaviour of cosmic ray particles in the Earth's magnetic field, and they led to a greater appreciation of the importance of the non-dipole components of this field. During 1955–59, Dr. Waddington held a Royal Society McKinnon research studentship which enabled him to continue his work in Bristol on the composition of the primary cosmic radiation, and the eleven-year variation in the intensity of these particles. During this time, 1957–58, he spent one year in the University of Minnesota. In 1959 he was appointed lecturer in physics in the University of Bristol—a post which he has continued to occupy until the present time. He spent six months at the National Aeronautics and Space Administration in the United States in 1961, continuing researches into the various aspects of primary cosmic radiation, and contributing to the development of techniques whereby photographic emulsions are used to detect temporal changes in the intensity of the primary cosmic radiation. Dr. Waddington is the author or the co-author of more than forty papers on subjects related to cosmic radiation.

Biochemistry, Nutrition and Food Science in Ghana
Prof. F. Aylward

The new Department of Biochemistry, Nutrition and Food Science in the University of Ghana is the first of its kind in Africa. The appointment of Dr. Francis Aylward as professor and head of this Department will ensure that this important development gets off to an excellent start. The Department will be concerned chiefly with courses leading to the degree of B.Sc. in Food Science, and with development and research in foods and food processes. Dr. Aylward's initial training was as a chemist and a biochemist. He was awarded first-class honours in chemistry at the B.Sc. examination in the University of Liverpool in 1932, and a Ph.D. in biochemistry in 1934. He has done research at the Hannah Dairy Institute in Ayr, in the Universities of Liverpool, Manchester and Johns Hopkins in Baltimore, and with Imperial Chemical Industries, Ltd. Recently, he was head of the Department of Chemistry and Food Technology in the Borough Polytechnic, London.

Dr. Aylward's publications demonstrate the growth of his increasing interests in the problems of food and nutrition. His early work was on the lipids, more recently, it has extended to studies on chemical additives to food and to investigations of dietary patterns and food habits. During the past two years, Dr. Aylward served as scientific adviser on foods and nutrition to the University of Ghana, on behalf of the Food and Agriculture Organization of the United Nations. He has produced a short but comprehensive report on foods and nutrition to the Government of Ghana (see p. 27 of this issue). The initiation of the new Department, with Prof. Aylward as its enthusiastic and versatile head, can be expected to serve as a model for other African countries in their attack on hunger and malnutrition.

Psychology at Hull:
Dr. A. D. B. Clarke

Dr. Alan D. B. Clarke, at present consultant psychologist and head of the Department of Psychology at the Manor Hospital, Epsom, has been appointed to the chair of psychology in the University of Hull with effect from October 1, in succession to Mr. G. Westby, who has been appointed to the chair of psychology in the University College of South Wales and Monmouthshire (see *Nature*, 192, 918, 1961). Dr. Clarke was appointed senior psychologist and head of the then new Department of Psychology at the Manor Hospital at Epsom in 1951, and under his guidance the Department has become one of the leading psychology units in Britain. His pioneer work on the training of mental defectives has revised all previous ideas on this subject and has been of the greatest social and psychological value

Dr Clarke is an active member of various committees of the British Psychological Society's Division of Professional Psychologists, and during 1954 he acted as secretary of the Society's Working Party on Mental Deficiency which prepared the memorandum of evidence submitted to the Royal Commission. His book *Mental Deficiency: the Changing Outlook* is considered to be one of the best on mental deficiency by an English-speaking psychologist, and he has contributed many papers to learned journals on clinical problems relating to intelligence, personality, learning in imbeciles and their employability, on social and emotional deprivation and also on general areas of psychology. With his wife, Dr Ann Clarke, who is also a psychologist at The Manor, he has recently been associated with the production of a documentary film on *Learning in Slow Motion* relating to their research. This film has been taken over for distribution purposes by the Central Office of Information.

Nuclear Power Research and Development in Britain

In a written answer in the House of Commons on June 4, the Parliamentary Secretary for Science, Mr. D. Freeth, stated that a design team had been established to consider nuclear ships by the Atomic Energy Authority in conjunction with the British Ship Research Association and other interested organizations. The principal systems being studied by the team were the steam-cooled and steam-generating heavy-water reactors and advanced designs of pressurized-water and boiling-water reactors. Contracts for design study work had been negotiated with the Nuclear Power Group, the United Power Company, Rolls Royce and Babcock and Wilcox. Work was also in progress on reactor physics, engineering development, fuel-element technology and reactor materials in support of the marine reactor systems. In a further answer, Mr. Freeth gave the estimated cost of the experimental advanced gas-cooled reactor which should come into operation within the next two months as about £9.7 million, and the annual outlay for the operation and maintenance of the Dounreay experimental fast reactor as at present being about £2 million. On June 5 he stated that organizations for which the Minister for Science was responsible supported research in seismology by twenty-four qualified scientists, of whom twenty were employed by the Atomic Energy Authority and four were supported by research grants from the Department of Scientific and Industrial Research. The Meteorological Office employed two further scientists and the Universities of Aberdeen, Cambridge, Durham, Edinburgh and Liverpool had departments participating in seismological research.

Petroleum in the United Kingdom, 1961

United Kingdom industry statistics relating to consumption and refinery production of petroleum and its products for 1960 and 1961 was published by the Petroleum Information Bureau in April 1962, on behalf of the U.K. Petroleum Industry Advisory Committee (*U.K. Petroleum Industry Statistics—Consumption and Refinery Production, 1960 and 1961*. Pp. 9. London: Petroleum Information Bureau, 1962). This reveals that the internal demand for petroleum products was 7.8 per cent higher in 1961 than in the previous year, total consumption (excluding bunkers for ships engaged in foreign trade) being 46,014,950 tons. The standard products as now classified include aviation fuels, motor spirit, industrial spirits (with industrial benzole), white spirit, kerosene (burning and vaporizing oils), derv fuel, gas, Diesel and fuel oils, lubricating oils and greases, paraffin wax and scale, propane and butane, bitumen, chemical feedstock, light distillate feedstock, and refinery gases. Aviation fuels show for 1961 a 22.3 per cent rise, motor spirit increased by 6.8 per cent, burning oil consumption was 4.9 per cent lower, notwithstanding a rise of 50 per cent for domestic heating boilers compared with the previous year, due to the greater demand in the number of small and medium-sized houses for oil-fired central heating. Derv fuel was 9.9 per cent higher, lubricating oils only 1.5 per cent up, bitumen 9.7 per cent increase, and deliveries of propane and butane rose by 34 per cent, on account of heavier use in industry as gas-making feedstock. There was a rise of 11.1 per cent in consumption of refinery gases, but deliveries of chemical feedstock, which in recent years have advanced extremely rapidly, remained almost static compared with 1960. An interesting note on tax effect on consumption of motor spirit is that the 3*d*. per gallon surcharge imposed by the 'little Budget' in July 1961 (consolidated in the 1962 Budget to produce a standard rate of duty of 2*s*. 9*d*. per gal.) caused a tendency for lower grades of petrol to be favoured at the expense of the super brands.

U.K. Attitudes towards Population Control

The question of population pressure in Asia was again raised in the House of Lords by Lord Casey on June 6, who specifically asked the Government what it proposed doing to stimulate scientific research in the United Kingdom towards a socially acceptable solution of the problem applicable to Asian conditions. Referring particularly to population growth in India and Pakistan and the introduction of family planning, Lord Casey urged the need for research into biological methods of contraception. However, other speakers in the debate, including Lord Adrian, were more cautious regarding the value of recent introductions mentioned by Lord Casey and stressed the need to consider the subject in the widest possible context, Lord Milverton expressing the view that no scientific solution of the problem could be other than an adjunct to long-term educational, economic and cultural influences. Lord Brain emphasized the same point of view, urging that the population question was not solely a matter of food for the body, and besides stressing education pointed out the risk of epidemics spreading through air travel. He suggested that careful watch should be kept for any short-term reactions in introducing new oral contraceptives and that the Government should hold a watching brief on clinical tests of all contraceptives, if they did not sponsor such tests themselves and give a lead to the World Health Organization.

In replying for the Government on the debate, the Parliamentary Under-Secretary of State for Commonwealth Relations, the Duke of Devonshire, said that the Government was well aware of the problem and he agreed as to the need to increase food supply. On scientific research, he said that research into methods of contraception was linked with research into the whole field of infertility and that both fields were closely connected with some lines of cancer research. There was no indication of a shortage of funds for any promising lines of work and there was close co-operation between scientists in Britain and in India and elsewhere. Much work on the physiology of reproduction was being undertaken in university

R 329

departments and by the Medical and the Agricultural Research Councils, in addition to a certain amount directly aimed at the control of conception, carried out by industrial enterprises. The Government would always be ready to accede to requests for help from Governments under the Colombo Plan. However, until such requests for technical assistance were received, Britain's main contribution to the problem of over-population should be to continue to give maximum support to the existing programme of capital aid and technical assistance. Such programmes would leave the Governments concerned free to judge how the help given could be best applied to overcome poverty and ignorance.

Forestry in Britain

IN his address to the Royal Society of Arts on the subject of forestry (the second of three Cantor Lectures on the Development of Natural Resources, May 14, 1962), Mr James Macdonald, deputy director-general of the Forestry Commission, dealt first of all with the productive side of forestry. Only some 7 per cent of Britain's land surface is covered with forests, which is a low figure compared with many European countries. The tree line in Britain is relatively low and exposure may be severe, thus preventing the use for forestry purposes of localities which would otherwise be suitable. On the other hand, tree growth in some localities is faster than on the Continent. As a result of plantings during the past forty years, the acreage under conifers (all exotic except the Scots pine) has increased and that under hardwoods has diminished. The distribution of age-classes is not ideal, there being an over-abundance of old hardwoods and a deficiency of old conifers. However, this state of affairs will be adjusted before very long, particularly with the conifers which are grown on shorter rotations than the hardwoods. It is considered that in the next seventy years production will be doubled from private forests and trebled from Forestry Commission forests. This increased production will be required in Britain, which in 1960 imported £456 million of timber. According to investigations by the Food and Agriculture Organization, the increasing deficit in the supply of timber will continue for the next few decades and there are some North American authorities who consider it probable that there will be no exportable surplus of timber from that continent by the end of the century. Forestry has an important part to play in upland areas in Britain, where it can increase production from the land and also help other land users with better communications and better grazing conditions without any diminution of livestock. The National Forest Parks provide facilities for recreation without interfering with the continued practice of forestry. Forests are also a haven for wild-life and thus help in its preservation. Mr Macdonald ended his talk by referring to the multiple uses of forestry in Britain, some of which are assessable in cash while others are not, but both private and State forests "represent a substantial contribution to national resources and a contribution which is growing greater year by year".

Materials Research

THE first number of a new international quarterly, *Materials Research*, was published in April (1, No. 1, April 1962. Published quarterly. Annual subscription £5. London: Heywood and Co., Ltd., 1962). The editors are Dr. E. G. Stanford (Banbury), Prof. T. J. Dolan (Illinois) and Prof. P. G. Bastien (Paris). Papers are in English, but abstracts of all the papers are printed in English, French, German, Italian and Russian. The sub-title of the periodical is "An International Journal of the Properties and Testing of Engineering Materials", and on the evidence of the seven papers included in the first issue, the emphasis is to be evenly distributed between these two fields. One group of papers is concerned with the use of ultrasonic flaw-testing equipment and with a rapid induction method for measuring electrical conductivity, while the other research papers deal with creep, notch-brittleness and an engineering aspect of fatigue. One of the declared aims of the periodical is to analyse the reasons for the particular properties of various materials. This aim has been pursued in an introductory review paper, which attempts a survey of the properties of metals in terms of crystal structure and two-phase distributions. In the light of this first issue, it appears likely that the journal will concern itself with comparatively empirical studies of engineering materials, together with an intensive examination of modern methods of materials testing and inspection. Since there is a shortage of journals dealing with testing methods, it is to be hoped that the editors will continue to give considerable space to good papers in this important field.

Topology

IN the course of this century, topology has grown from some isolated and special problems into one of the major disciplines of modern mathematics, with a considerable terminology and an array of methods which are influencing almost every other branch of the subject. The untimely death of that great topologist, Henry Whitehead, has fortunately not prevented his project of an international journal for topology from coming to fruition, thanks to the scientific enterprise of the Pergamon Press (*Topology*. Vol. 1, January–March, 1962. An International Journal of Mathematics founded by J. H. C. Whitehead, Oxford. Pp. 80. Published four times yearly. London and New York: Pergamon Press, 1962. Annual subscription rates: *A*, for libraries, government establishments, research laboratories, etc., £10 or 30 dollars; *B*, for individuals who place their orders directly with the publisher and certify that the journal is for their personal use, £3 10*s*. or 10 dollars). The new journal is a quarterly, and the first part appeared in the spring of this year. There is a strong editorial board consisting of M. F. Atiyah (Oxford), R. Bott (Harvard), F. Hirzebruch (Bonn), I. M. James (Oxford), R. Thom (Strasbourg), and an editorial advisory board of great distinction: H. Cartan (Paris), K. Kuratowski (Warsaw), M. H. A. Newman (Manchester), H. Seifert (Heidelberg), N. E. Steenrod (Princeton).

South African Museum, Cape Town

To an increasing extent museums are now seeking to advance knowledge by research and publication, and this is in addition to their previous functions of acquisition and conservation. In a recent issue of *Annals of the South African Museum* (46, Part 9: *On the Dentition and Tooth Replacement in Two Bauriamorph Reptiles*. Pp. 231–256+plates 12–14. Cape Town: South African Museum, 1962. 52 cents), Dr. A. W. Crompton gives the results of his researches on the dentition and tooth replacement in two Bauriamorph reptiles (*Ericiolacerta parva* and *Bauria cynops*). He finds that alternate tooth replacement was present in both genera *Ericiolacerta* represents an early stage in the transition from a sectorial to a pounding or crushing dentition, but it is doubted whether a true grinding action was present in *Bauria*

Biological Objects in Plastic

It has become increasingly the custom in Museums to embed various biological specimens in plastic and thus preserve colour and shape far better than by the older methods Messrs G Notini and Sigrid V Wettstein have just published in the *Bulletin of the Royal School of Forestry, Stockholm* (*Kungl Skogshogskolans Skrifter* Nr 36 "Embedding Biological Objects in Plastic" Pp 34 Stockholm Emil Kihlstroms Tryckeri AB, 1961) a very useful paper with full descriptive notes of the technical work involved The authors have carried out a prolonged investigation on this subject, and the paper includes details not only of the preparation of objects for embedding but also of the actual embedding procedure and the details as applied to the following types of objects Lepidoptera, Coleoptera, Hymenoptera, Diptera, spiders, fishes, crustaceans, centipedes reptiles, small mammals and anatomical preparations Also included is a useful list of references to previous work

Semiconductors and Transistors

The Special Subject List No 36 of the Library Association, entitled *Semiconductors and Transistors*, has been compiled by E H C Driver, librarian of the College of Advanced Technology Birmingham (Pp 19 6*s*, Library Association members, 4*s* 6*d* London The Library Association, 1961) It contains a preface by Prof R A Smith, University of Sheffield, and represents an adequate, but obviously not complete, bibliography of the large and rapidly growing literature on the subject Books published earlier than 1955 have been included only if especially useful and most of the entries refer to the years 1959–62 The 63 entries, apart from a separate list of periodicals, are grouped under the headings guides to the literature, abstracts, surveys and reviews, definitions, standards, and a select book list divided into five sections Popular paper-backs on transistor circuits for the home constructor have been excluded No prices of books are given and the entries have been limited to texts in English The List, which concludes with an excellent index, should be most helpful to those searching the literature or wishing to commence a small collection of books on the subject of semiconductors

The National Meteorological Library

Now that the Meteorological Office is fully established in its new building at Bracknell, Berkshire, its library is properly housed in suitable accommodation, and, except for its geographical location, is fully accessible Some of the material stored is on open shelves, and there are large stock rooms to which readers are not normally admitted The reading room is large and pleasant, with card index and loan facilities readily available The indexing is thorough, and in addition to the usual author-index there is a comprehensive subject-index which is based on the Universal Decimal Classification In this the author and title of every paper held on each subject are listed in chronological order A considerable number of translations of foreign literature are held, and this store is being continually augmented There is a room set aside for viewing micro-films and micro-cards These valuable facilities are available to the public for *bona fide* purposes

Testing Ferrous Metals for Corrosion Resistance

A useful booklet has been prepared by Mr K A Chandler for the Methods of Testing (Corrosion) Sub-Committee of the British Iron and Steel Research Association (*Testing Ferrous Metals for Corrosion Resistance* Pp 27 (MG/BF/19/61) London British Iron and Steel Research Association, 1962 3*s* 6*d*) In this he discusses a number of simple corrosion-testing procedures which require neither specialized experience nor complex equipment Designed, in the main, to meet the needs of small and medium-sized firms, it starts with a general introduction and then goes on to consider the choice of test and the preparation of specimens Laboratory tests are dealt with in the longest chapter and followed by field tests and service trials The final chapter is a very helpful account of the assessment of the results in terms of practical behaviour

Utilization of Activated Sludge

The activated sludge process is an aerobic and rapid method of sewage purification, which yields a sludge that settles down quickly, leaving a clear, well-oxidized effluent These changes are essentially brought about by micro-organisms which thrive in sewage under aerobic conditions Since the early days of the development of the process, attempts have been made to utilize activated sludge for agricultural purposes In recent years the possibility of utilizing sludge more directly as a feed supplement for animals has been investigated An article by S Sathyanarayana Rao and S C Pillai, of the Department of Biochemistry, Indian Institute of Science, Bangalore, gives a brief account of the studies, particularly on vitamin B_{12}, in activated sludge and on the utilization of the sludge as a feed supplement for farm animals, such as chicks and pigs (*J Sci Indust Res A* General 21*A* No 1, 1962) The work was started soon after the discovery of vitamin B_{12} and recognition of its importance in the nutrition of man and animals There is already some evidence to indicate the value of activated sludge as a feed supplement In addition to certain nutrients, activated sludge also may contain other substances as a result of intense microbial activity Activated sludge concentrates coenzyme $Q'2$, and it may be considered as a source of coenzyme Q in view of the recent attempt to produce it by bacterial fermentation of certain synthetic media

The Royal Commission for the Exhibition of 1851 Awards

The following awards for 1962 have been announced *Senior Studentships* K Bearpark (University of Oxford) for research in physics at Oxford, J F P Hudson (University of Cambridge) for research in mathematics at Cambridge, D I John (University College, Swansea, and Imperial College of Science and Technology) for research in organic chemistry at Imperial College, J R Waldram (University of Cambridge) for research in physics at Cambridge *Overseas Scholarships* (1) *Canada*, M C L Gerry (University of British Columbia) for research in physical chemistry at Cambridge, P Copper (University of Saskatchewan) for research in geology at Tubingen, J J Simpson (University of Toronto) for research in nuclear physics at Oxford, (2) *Australia*, J D Cotton (University of Melbourne) for research in inorganic chemistry at Cambridge, J L Black (University of Melbourne) for research in nuclear physics at Oxford, B D Jones (University of Sydney) for research in mathematics at Glasgow, (3) *New Zealand*, J F Young (University of Canterbury) for research in inorganic chemistry at Imperial College of Science and Technology, (4) *Pakistan*, E Ahmed (University of Dacca) for research in theoretical physics (place of study to be arranged), (5) *Singapore*, Miss P. H Yuen (University of Singapore) for research in zoology at the London School of Hygiene and Tropical Medicine; (6) *Republic of Ireland*, R E Burton (Trinity College, Dublin) for research in theoretical chemistry at Oxford.

Courses in Applied Mechanics

THE Postgraduate Department of Applied Mechanics of the University of Sheffield will hold the following introductory courses during the academic year 1962–63 electronics for engineers, stress determination, fine measurement in mechanical engineering, gear design, analysis of failures of machines and structures, corrosion and fatigue, non-destructive testing, hydraulic operation and control of machines, servomechanisms and automatic controls, gear loading, stress and life, friction wear and lubrication, analogue computing methods for engineers, noise, mechanical vibration, techniques in control engineering The courses are open to graduates in engineering or related subjects and to those with comparable technical training Further information can be obtained from Prof W A Tuplin, Department of Applied Mechanics, University of Sheffield, St George's Square, Sheffield

Physics Department at Stanford University

IN the note entitled "Nobel Prize for Physics Prof Robert Hofstadter" that appeared on p 799 of the December 2, 1961, issue of *Nature*, it was stated that Prof Hofstadter became head of the Physics Department at Stanford University Prof Hofstadter writes that this does not agree with the facts "Prof Leonard Schiff has been Executive Head of the Physics Department at Stanford University since July 1, 1948 Under his leadership the Physics Department has made many significant contributions to the field of physics Throughout this long period Prof Schiff has consistently been active in theoretical physics and he himself has made important progress in many different fields of physics" Prof Hofstadter is, in fact, a member of Prof Schiff's Department.

University and College News:

College of Aeronautics

THE following appointments have been announced J R Busing, to be senior lecturer in the Department of Aerodynamics, K H Griffin, to be senior lecturer in the Department of Aircraft Design, D Hyde, to be lecturer in the Department of Flight, D W McQue, to be instrumentation engineer in the Department of Electrical and Control Engineering, W G. Bradley, to be Research Fellow in the Department of Flight

Edinburgh

THE following appointments to lecturer have been made· Dr M M Harding (chemistry), Dr A L Haigh (veterinary physiology), Dr P Walker (zoology), Dr M Williamson (zoology)

Keele

THE following appointments and promotions have been made Dr I M L Hunter to be professor of psychology, R Shaw to be director of extra-mural studies, *Readerships*, Dr D E Davies (physics), Dr R McWeeny (chemistry), Dr R G Evans (biology), *Senior Lectureships*, Dr P Halmos (psychology), Dr C S Exley (geology), Dr S C Nyburg (chemistry). Dr P H Plesch (chemistry)

London

THE following titles have been conferred that of professor of zoology on Dr P M Butler in respect of his post at Royal Holloway College, that of professor of mathematics on Dr A Frohlich in respect of his post at King's College, that of professor of philosophy with special reference to sociology on Dr E A Gellner in respect of his post at the London School of Economics and Political Science, that of reader in comparative education on Dr E J King in respect of his post at King's College, that of reader in physics on Dr B Donovan in respect of his post at Westfield College The following appointments have been made Dr J Naylor Hunt, to the chair of physiology tenable at Guy's Hospital Medical School, Dr R W H Sargent, senior lecturer at the Imperial College of Science and Technology, to the chair of chemical engineering tenable at that College, Mr W G Spector, senior lecturer at University College Hospital Medical School to the chair of pathology tenable at St Bartholomew's Hospital Medical College, *Readerships*, Dr M E Fisher (physics), Dr A N Davison (biochemistry), Dr J A Elvidge (organic chemistry), Dr P J Higgins (mathematics) Dr D Robinson (biochemistry), J L Stafford (hæmatology), Dr M B Thorn (biochemistry)

University College of Swansea

THE following appointments to lectureships have been made for the session 1962–63 Mr F T M Smith (applied mathematics), Dr. C. A Wellington (chemistry), Mr M J Clarke (mechanical engineering), Mr D A Watts (geography)

Announcements

DR DENIS TAYLOR, who for the past five years has been a director and general manager of Plessey Nucleonics, Ltd , has been appointed co-ordinator of research and development for the Plessey Co , Ltd At one time Dr Taylor was head of the Electronics and Instrument Division of the Atomic Energy Research Establishment, Harwell

THE Joseph P Kennedy Jr Foundation is offering three international awards to recognize significant achievements in the past and to assist efforts of outstanding promise in research, service and leadership concerned with mental retardation Further information can be obtained from the Joseph P Kennedy Jr Foundation, 1413 K Street, N W Suite 306, Washington 5, D C

A MEETING of the British Biophysical Society will be held in the Laboratory of Molecular Biology, University of Cambridge, on September 27 The programme will include a talk by Dr M F Perutz Further information can be obtained from Dr Herman Watson, Laboratory of Molecular Biology University Postgraduate Medical School, Hills Road Cambridge

THE sixth plenary meeting of the World Power Conference will be held in Melbourne during October 20–27 Further information can be obtained from the British National Committee, World Power Conference, 201–2 Grand Buildings, Trafalgar Square London, W C 2.

THE QUEEN'S UNIVERSITY OF BELFAST

NEW PHYSICS BUILDING

THE old physics building at the Queen's University of Belfast, which was built shortly before the First World War, has become increasingly inadequate for the needs of the Department since 1945. Temporary extra accommodation has been provided in two groups of three huts and a house, but these were scattered and have shortly to be taken down or used for other purposes. They have now been replaced by a substantial extension to the old building, which was opened by H.M. Queen Elizabeth, the Queen Mother, on April 6.

The new building, which is seen from the north in Fig. 1, is joined to the old building by two curved corridors (beyond the left) at ground-floor and basement levels. It occupies most of the space along the city park boundary between the University's main assembly hall (at the right) and the old physics building. The principal part is a four-storey L-shaped structure concave to the boundary, with, under part of its area, a large sub-basement boiler house serving a number of buildings, and a smaller ventilating-plant room for the basement and ground-floor of the new physics building. There are also tank rooms and a second ventilating plant on the roof, and a new workshop connected to the lower link corridor, between the park boundary and the old building, but structurally separate from the latter. Goods can be delivered from the rear of the building to a two-ton lift giving access to most parts of both the old and new buildings. The main store-rooms are located off the link corridors. Water and gas feeds are generous, and the central switch-room is supplied from an individual 500-kW. sub-station the capacity of which can be doubled later if necessary.

The new building has two lecture rooms. The larger, seating 280, is situated at the south-west end. As it will also be used for general university purposes, it has a separate entrance and separate services from the rest of the building, and contains a number of projection units which are not at present usually considered necessary for physics teaching. The smaller, seating 100, is on the first floor above a ground-floor library and reading room and the boiler house.

The ground, first and second floors will carry uniform loads of approaching 240, 180 and 120 lb./sq. ft. respectively. The bulk of the room heating in all three of these floors and the basement is by hot water circulating in acoustically treated ceiling panels. The layout is such that the uses of most sections of the building can be varied substantially. The initial allocation of space will probably be: basement, research and service rooms; ground floor, office, staff and research rooms; first floor, third- and fourth-year undergraduate teaching laboratories; second floor, second-year undergraduate teaching laboratories.

The old building is to be rehabilitated during the session 1962–63. When it is again available, the

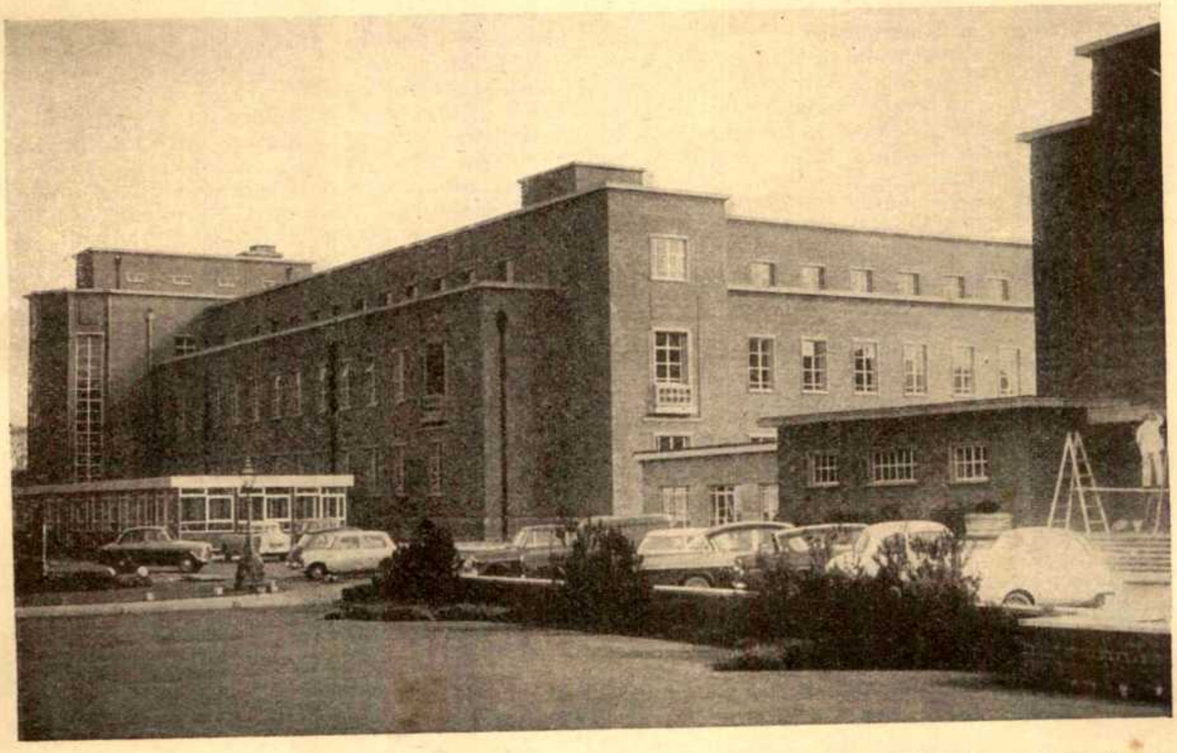

Fig. 1. Physics Extension Building, Queen's University of Belfast. The building to the right is the University assembly hall, the Whitla Hall; the small building between it and the Physics Building, and the small building to the left front of the Physics Building, are a temporary refectory and library reading room, respectively (*Photo: by courtesy of the Northern Whig, Ltd., Belfast*)

first floor of this will be used for the first-year undergraduate teaching laboratory. The total useful floor space in the old and new building will be somewhat over 60,000 sq. ft. The number of physics students in all years has been nearly 1,000 in the session 1961–62; future numbers will depend on the University's policy about limitation.

The architect of the building was Mr. John MacGeagh, the principal contractors Messrs. F. B. McKee and Co., Ltd., and the engineering consultants Messrs. Oscar Faber and Partners. The Department's interests have been attended to by Dr. R. H. Sloane, reader in physics. The total cost has been about £800,000.

EXPERIMENTAL TAXONOMY

THE annual symposium of the group for experimental taxonomy of the Linnean Society of London was held on March 2, at the Society's rooms in London. After a brief introduction from Prof. D. H. Valentine, the meeting began with a paper by Dr. D. M. Moore (University of Leicester), on "Speciation within Chilean Clarkias". The annual genus *Clarkia* contains some 34 species in western North America, and a series of forms from central Chile and adjacent regions of Argentina which are presently included under *C. tenella* (Cav.) Lewis and Lewis. *C. tenella* is tetraploid and has been shown to be closely related to *C. davyi* of coastal California by Raven and Lewis, who suggested that South American plants resulted from trans-equatorial long-distance dispersal in late Pliocene or more recent time. Data were presented to illustrate the pattern of variation within the Chilean species of *Clarkia* and its correlation with the breeding system. It was suggested that the ancestral introduction was close to the large-flowered outcrosser, with $n = 17$, which occurs in southern central Chile; and a scheme was outlined to suggest the derivation of the other South American forms from this type. Some populations of outcrossers, separated from the others and representing the southernmost occurrence of the genus, have lost a pair of chromosomes but are morphologically identical with the 17-chromosome form. Most differentiation was shown to be associated with the change to autogamy, which generally involves no change of chromosome number. Self-pollinated forms have the stamens and style of equal length ; anthers and style mature simultaneously and are in close contact. The most widespread form has small flowers, is markedly self-pollinated and shows a whole range of biotypes usually differing slightly from one another, though occasional more extreme deviants are found. Populations intermediate morphologically between these small-flowered self-pollinaters and the outcrosser are facultatively outcrossing, though primarily self-pollinated, suggesting a gradual change to autogamy. Another entity sympatric with, but temporally quite isolated from, the outcrosser has acquired self-pollination without other marked morphological change. In only one case do self-pollinating plants show a different chromosome number, $2n = 28$; they are also remarkable for their yellow flowers, which are very rare in the genus. This scheme was discussed in relation to the frequent independent origin of self-pollinating from outcrossing forms within *Clarkia*.

The second paper, by Dr. A. J. S. Davies (Chester Beatty Institute), was entitled "A Cytogenetic Study of 28 Species of the Genus *Lathyrus*". The genus as a whole contains some 110 species occupying marginal and open habitats. Many morphological characters are used in the comparison of phenotypes in the traditional taxonomy of the group, and evolutionary trends in some of these can be postulated. The bracts at the base of the pedicel provide a useful indication of whether a species is specialized or not; there is a trend from long leafy bracts, to shorter, to a state where they are represented by a tuft of hairs. The genus is predominantly diploid ($2n = 14$) and gross chromosomal changes have probably not played a large part in its evolution. It is thought that there has been a tendency for chromosome-length to decrease and for the karyotype to become more asymmetrical, and this trend is associated with a decrease in plant size. Attempts have been made to cross fourteen of the annual species; and it has been shown that embryo abortion is the main barrier to interspecific hybridization. Hybrid plants have, however, been raised from four combinations of species. One of these was taken to the F_2 generation, and it was shown that at least four major gene loci are common to the parental species. Two of these genes, however, were modified in their expression in the F_2, indicating differences in the genetic background of the two species involved.

Dr. C. D. K. Cook (University of Liverpool) gave the next paper on "Variation in *Ranunculus* subg. *Batrachium*". He noted that the number of taxa recognized from the time of Linnæus to the present day ranged from 1 to 108; the number of new names per decade follows a normal curve of distribution. Much of the confusion in the group is due to the wide range of phenotypic plasticity shown by the species and the inability of workers to distinguish it, in the herbarium, from genotypic variation. In cultivation, a great deal of variation, both genotypic and phenotypic, is revealed. Thus, the achene number in both British (Isle of Wight) and Finnish (Helsinki) topodemes of *R. baudotii* varied from 10 to 60; but under experimental conditions, they differed in the average number of achenes produced in still and flowing water. Their total plasticity-range was, however, the same, and they are best regarded as two parts of a cline, with different ecological preferences. Extreme phenotypes occasionally become genetically fixed; an example is provided by plants of the alpine state of *R. trichophyllus*, some of which retain their original shape when cultivated in lowland conditions, and some of which revert to normal. The transition between capillary and laminar leaves in the group is always abrupt and is affected by length of day and temperature, but it is primarily under genetic control. Many hybrids are known. Some are infertile but very persistent, for example, some pentaploids in the *fluitans* group. Other species form fertile hybrids which are often unstable and unlikely to persist, but great variability in the F_2s has been demonstrated, and some of these, which differ greatly from their parents, may occasionally be able to invade new habitats.

Dr. A. J. E. Smith (University College, Swansea) then gave a paper on "Variation in *Melampyrum* *pratense*". This semi-parasitic species is difficult to raise from seed, but experiments have shown that it will grow on a variety of woody plants, such as species of *Betula*, *Calluna* and *Rubus*. It is very variable, 28 intraspecific taxa having been described, and much of this variation follows geographical trends in the British Isles. Plants become shorter in the north, and this is correlated with a reduction in the number of leaves and branches. The leaves also become shorter in the north and west. Anther-length is 20–30 per cent shorter in Northern Ireland than elsewhere. Superimposed on this clinal and geographical variation is ecological variation, the leaf width/length ratio divides the populations into those of calcareous and acid habitats, but the distinction is not clear-cut. Population samples were grouped according to habitat types and an analysis was made of the variation, using 8 vegetative and 3 floral characters, all of them quantitative. This showed that there was random distribution of genes or gene combination in the small isolated populations in which the plant occurs, and that similar groups of characters occurred in similar habitats. Some populations had cleistogamous flowers and were effectively inbreeding units. The variation pattern in certain morphological characters was, however, markedly different from that observed on the Continent.

Dr. J. K. Morton (Birkbeck College) gave the final paper on "Introgression in West African *Eulophia* Orchids". Two species, *E. cristata* and *E. millsoni*, were studied in the Accra coastal plains where their hybridization is associated with the disturbance caused by peasant agriculture, although their ecological preferences are different. Populations were analysed in order to discover the extent and direction of the apparent introgressive hybridization which was taking place. Ten characters associated with the structure of the flower and inflorescence were scored, such as height of inflorescence, number of flowers, and angle of lateral lobes of the lip to the horizontal, the introgression was demonstrated by pictorialized scatter diagrams and histograms. A remarkable feature which emerged was the unilateral gene-flow, back-crossing to the *E. millsoni* parent being frequent while none to *E. cristata* was detected. The introgression affected the biology of the populations, the *millsoni* hybrids extending the range of the species. Vegetative features were not included in the introgression studies since the leaves appeared 2–3 months later than the flowers.

The general discussion was opened by Dr. V. H. Heywood (University of Liverpool), who commented that the day's papers illustrated the tendency of botanists to emphasize breeding systems and dispersal mechanisms in consideration of speciation and adaptation, while zoologists place greater emphasis on phenotypic plasticity. He suggested that botanists should pay greater attention to the adaptive role of plasticity: they should not only be concerned in experimental taxonomy with determining genotypes, but also with the way that particular phenotypes may be selected. Given a range of expression of a particular genotype, only certain parts of that range will be selected in particular areas; this was well shown by Dr. Cook's paper on Batrachian *Ranunculi*. The problems of the taxonomic recognition of plasticity have also not been adequately considered.

Other points of importance which arose out of the papers were the effects of changes in the breeding system from outbreeding to inbreeding, the lack of synchronization of karyotype evolution with morphological and other genic evolution, as in *Lathyrus*, and the polytopic origin of taxa, such as had been suggested in the water buttercups and in *Melampyrum*. The question of long-distance dispersal in *Clarkia* was raised, and a discussion ensued, in which Dr. Gillet, Dr. Jones and Prof. Valentine took part. There was also a brisk exchange of views on the likelihood of the polytopic origin of species, especially in polyploid groups.

D. H. VALENTINE

FOOD TECHNOLOGY IN GHANA

To many people nutrition means no more than the study of foods and their use by the living body. But with increasing evidence of widespread malnutrition throughout the world, and of a deteriorating situation in regard to world population and food supplies, much emphasis needs to be placed on the importance of work outside the laboratory on problems associated with providing people everywhere with an adequate diet. In many parts of the world an immediate problem is a means of conveying foods from one place to another. For example, fruit, the sale of which provides a livelihood for some people, may be rotting on the trees because there are no roads on which it can be transported to other people who might benefit by addition of fruit to their diet. Sometimes roads exist, but mechanical transport is inadequate or excessively costly. Lack of adequate means of distribution may seriously limit the use of fish, and while many people suffer the effects of protein malnutrition, fishermen not far away suffer economic disaster because they cannot get rid of harvest gluts. Not only are roads and mechanical transport involved in the distribution of foods but in addition a means of preservation through cooling, drying or other means.

Ghana is a country where transportation and preservation of foods are of great importance. Owing to the geographical features of the country adequate diets can only be ensured when there is a free exchange of foods grown in the north with those grown in the south. The Government of Ghana has wisely taken steps to deal with nutritional problems, and has included food technology in its programme. The Government has called on the World Health and the Food and Agriculture Organizations for assistance in developing a public health nutrition programme, Dr. Francis Aylward, as Food and Agriculture Organization consultant (see also p. 20 of this issue), has recently examined problems of food supplies and nutrition in Ghana and has submitted a report on this subject*.

Dr. Aylward's report is a most useful one, not only for those interested in Ghana, but for many others as well The results of inquiries made under the auspices of United Nations' specialized agencies are in the first instance of a confidential nature and are designed to help the Governments concerned However, many excellent accounts are frequently being composed, which could be most useful to workers in special fields, and to administrators in many countries Such a report is that under discussion, and it is to be hoped that if the Government of Ghana receives requests for copies of the report it will be willing to assent to its distribution

---

* *Report to the Government of Ghana on Foods and Nutrition*. By Francis Aylward. ETAP Rep. No. 1449. (Food and Agriculture Organization of the United Nations, Rome, 1961.)

Dr Aylward has dealt systematically with many aspects of food technology and its relation to the provision of adequate diets He has wisely emphasized inherent economic and social dangers of thoughtless introduction into a developing country of new techniques Such is the perversity of man that valuable methods of preserving much-needed food may be diverted to less needy ends Thus one of the most important recent changes in Ghana noted by Dr Aylward is the introduction of ice-plants which provide refrigeration for the storage of animal products, but refrigeration is now also being used to an appreciable extent for cooling commercially prepared soft drinks This is not necessarily to be deplored, but administrators must be aware that when they sponsor the introduction of a given technique for one end, it may be used also for less-worthy, and sometimes undesirable, purposes

Usually modern techniques lead to the production of foods which are more expensive than the original materials When the product enables some people to obtain foods necessary for their well-being and which they would not otherwise obtain the cost must be ignored But very often a new product, especially if it is commercially advertised, is regarded as of particular value and may be purchased at unwarranted expense by those not specially in need of it In developing countries this is unfortunate and may be a factor leading to malnutrition among sophisticated urban groups Any means, therefore, of producing food products cheaply is to be encouraged Perhaps one of the most significant advances in this connexion has been the use of plastics for food packaging Not only is this kind of material cheaper than metal containers, but also it may provide a better means of preservation than some alternatives Dr Aylward directs attention, for example, to the satisfactory use of plastics in the storage of fish meal produced in Ghana

Proposals have been made for the introduction into Ghana of 'filled milk' composed of skimmed milk powder, water and coconut oil This poses a troublesome problem for public health administrators Though such a milk product may be produced relatively cheaply in some circumstances, thus leading to its widespread use among the poor and needy, there is not yet enough evidence of the effects, especially on infants, of repeated ingestion of coconut oil which contains a high proportion of saturated fatty acids, and also a good deal of lauric acid It is often the case that new preparations of food such as filled milk are readily accepted by the public before administrators are in a position to control their use should this be necessary

While it is true that the application of scientific methods in the growth, storage and preparation of foods carries possible hazards, it is of the greatest importance, as Dr Aylward states, to realize that food technology has developed in order to meet the urgent problems associated with feeding ever-enlarging urban communities, modern food industries are essentially a response to public needs "And it is precisely for this (as well as other reasons) that the food scientist and technologist has a role to play in Ghana" G R WADSWORTH

CHOOSING FOREST SPECIES

WORLD requirements for wood and wood products are steadily increasing, though the forms in which it is being used and the kinds of timber most in demand are constantly changing World forest resources, which are badly distributed in relation to centres of consumption, are becoming inadequate to meet requirements, and acute shortages are already being felt At the same time, many natural forest types have relatively low production, and the kinds of wood produced are often not those most in demand

This is particularly true of vast areas of tropical forest where the luxuriance and variety of the growth make them economically a poor proposition Many of the species in them are hard, heavy and difficult to season, and are unsaleable Even in Europe, the large areas of oak forest, often of low quality, which used to meet demands for fuel and heavy constructional timber are becoming a burden on the market If future demands for wood are to be met in the quantities and in the kinds of product required, it will be necessary to improve the productive efficiency of forests all over the world, and to grow more intensively those particular species that will be most in demand The kind of species most likely to be favoured have recently been discussed by Prof M V Laurie of the University of Oxford (*Span*, 5, No 1, 1962)

It is difficult to estimate what will be wanted half a century or more ahead, but this is what the forester has to try to do when formulating his objects of management and considering what species he ought to be growing Heavy timbers have largely disappeared from constructional uses On the other hand, softwoods are still used in large quantities for house building and other structural purposes, and recent developments in laminated construction have provided new outlets for softwood timber in short lengths and of relatively low quality

Present indications are that softwoods will be in greater demand than hardwoods for most purposes, and that general purpose timbers, which at the same time can be used for core stock or laminated construction and can be chipped or pulped, are most likely to be wanted in large quantities in the future This trend is already reflected in the large programmes for planting conifers in many parts of the world Although it may not be difficult to envisage the kind of trees that are likely to be needed to meet future requirements, the question of what can be grown on the sites available is more difficult to answer Here the limitations of climate, soil and biological agencies are crucial Different species vary greatly in their tolerances of conditions differing from those of their native habitat, so much so, in fact, that it is impossible to say with any degree of certainty whether exotic species will succeed or fail purely from a comparison of conditions in their native land with those in the locality of introduction

As an example, the Monterey pine, *Pinus radiata*, from a restricted area in California, has been outstandingly successful in New Zealand, many parts of Australia, in South Africa, Spain and Chile, and it even grows well in the highlands of Kenya Again, the Serbian spruce, *Picaea omorika*, which grows on limestone mountains in a very restricted area in Yugoslavia, grows remarkably well on acid peats in Scotland In other cases, the reverse may be true, and many species which have a wide natural range, like the Douglas fir or European larch, have developed local strains which are susceptible to the conditions under which they are grown The only safe way of selecting a species for introduction is to try it, and all large-scale plantings of exotic trees have been preceded by species trials in arboreta or small trial plots where suitability to the locality is tested, followed by larger plot tests on a more limited range of sites where performance can be estimated

There are many doubts and risks in introducing an exotic species into a new habitat, and it should always be a principle first to see whether any indigenous species will fulfil the objects in view The principle that one should not consider introducing an exotic species on a large scale if there is an indigenous species that will meet requirements is generally true In countries like Britain, however, where the only native timber-yielding conifer, the Scots pine, grows relatively slowly, there is a good case for introducing species that will give higher yields It is fortunate that some of the conifers from the west coast of North America, Sitka spruce, Douglas fir, western hemlock and lodgepole pine, as well as some from Europe, such as Corsican pine, Norway spruce, European larch and, more remotely, the Japanese larch, have proved so successful in Britain Trials have shown that many species, particularly those from the eastern parts of North America, suffer so seriously from late-spring frosts in Britain as to be not worth growing Most species of *Eucalyptus* are found to be too susceptible to frost to be grown safely in Britain, except in sheltered parts of Devon and Cornwall Corsican pine, when moved to northern British latitudes, is found to be restricted in the elevation at which it can be grown Teak does not grow well on very heavy soils or on laterites in the tropics and needs some lime in the soil, it seems to require a definite dry season when it is leafless No amount of information can enable a species to be accepted as safe for large-scale planting without extensive trials

It frequently happens that a particular species is so superior in performance to all others tried that there is a tendency to rely on it alone in large plantation programmes This has occurred, for example, in New Zealand and parts of Australia where *Pinus radiata* has been planted extensively. So far there has been no serious trouble, but there is always the danger that something may go wrong It is advisable to have one or more alternative species to fall back on in an emergency

In South Africa, for example, *P radiata*, which showed great promise to start with, has more recently suffered severely from a fungal disease which kills the leading shoot There is now a tendency to prefer *P patula*, another fast-growing pine, which does not suffer from this defect

ERADICATION OF MALARIA IN EAST AFRICA

In the annual report of the East African Council for Medical Research[*], the director of the East African Institute of Malaria and Vector-Borne Diseases, Dr G Pringle, describes how a draft plan has been prepared for the eradication of malaria from East Africa, based on a combined attack with drugs as well as insecticides The plan has already received critical examination by a meeting of experts held in Tanga, and further inter-territorial consultations are planned

In the Taveta-Para area, where spraying with dieldrin was discontinued early in 1959, a close watch on malaria incidence has been kept *Anopheles gambiae* has shown a marked increase in numbers, although house catches have still been less than pre-spraying densities The longevity of this vector is still reduced, indicating the presence of some continuing insecticidal effect *A funestus*, which was almost certainly eradicated from the area, has not reappeared Although parasite densities are not back to former levels, there has been a major resurgence of the disease in the swampside villages Studies of the serum γ-globulin levels in schoolchildren also indicate that an effective immunity has yet to be acquired

The feeding preference of *A gambiae*, in areas where man and cattle are both attacked, has been studied with the view of finding out whether the individual mosquitoes show a consistent tendency to feed on one or other host Results in one area are still inconclusive, but in another district the presence of normal infection-rates in insects caught feeding on cattle clearly showed that the same mosquitoes had fed at different times on both available hosts Thus, so far, no evidence has been found of two co-existing strains of *A gambiae*, differing in their feeding habits, and hence probably in their response to insecticides

Among potential secondary vectors of malaria, infections have been found in *A pharoensis* and *A squamosus*, but none in the more abundant and ubiquitous members of the *A coustani* group Age-grouping studies indicate that, in all these species of exophilic mosquitoes, longevity is greatly reduced compared with the main house resting vectors

A flourishing colony of the coastal salt water form of *A gambiae* has been established Crossing experiments with two strains of fresh water *A gambiae* have shown that, although occasional fertile offspring are produced, a formidable barrier to gene exchange exists Thus reproductive isolation of the two groups in Nature seems likely, although proof of this has yet to be obtained in the field

DETECTION OF THE MICROWAVE ν_{27^-} LINE OF MOLECULAR OXYGEN PRODUCED IN THE HIGH ATMOSPHERE

By W. KAHAN

Columbia Radiation Laboratory, Columbia University, New York

RADIOTELESCOPE observations of atmospheric absorption of solar millimetre wave radiation have resulted in the detection of the ν_{27^-} telluric molecular oxygen line at 53,070 Mc /s Furthermore, measurements made on different days have shown that the peak of the ν_{27^-} molecular oxygen absorption varies in intensity, presumably as a result of temperature variations in the Earth's high atmosphere where the pressure is low enough to produce the line peak observed Because the wings of the line are primarily due to high-pressure absorption, high-altitude temperature changes could greatly vary the vertical atmospheric absorption at the centre of the line without appreciably affecting the off-centre portions

Atmospheric absorption in the 0 5 cm wave-length region is largely produced by the oxygen molecule, which in its ground-state, $^3\Sigma$, has an electronic spin $S = 1$ which couples to the odd integral angular momentum, N, of the end-over-end rotation of the dumbbell molecule to produce states of $\mathbf{J} = \mathbf{N} + \mathbf{S}$ (ref 1) The permitted transitions $J = N \rightarrow J = N + 1$ and $J = N \rightarrow J = N - 1$ give rise to lines at frequencies denoted respectively by ν_{N^+} and ν_{N^-} which lie primarily near 60 kMc /s There are 34 molecular oxygen lines between 51 kMc /s and 68 kMc /s which combine to produce a highly attenuating frequency region for microwave transmission through a vertical column of the Earth's atmosphere

The central frequency portion of the attenuating region is almost completely opaque because the high intensity and pressure broadening of the oxygen lines bring the vertical atmospheric transmission down to less than 10^{-6} over an extended frequency interval Consequently, it is not feasible to use the Sun as a blackbody radiator and to measure, with a radiotelescope near sea-level, an individual telluric molecular oxygen absorption peak in the opaque region where receiver intensities corresponding to antenna temperatures of 10^{-3} ° K and 10^{-8} ° K would be typical for respectively the wings and the peak of an absorption line A millimetre-wave radiometer is unable to distinguish between such low intensities Away from the central opaque region, the molecular oxygen transitions originate from progressively higher rotational quantum states and are less intense as a result of the decrease of state population with increasing N

The experiments described in this article were done on the ν_{27^-} line, where N is high enough for the detection of an isolated molecular oxygen absorption peak to be possible The frequency ν_{27^-} had not been previously measured, and its value was computed from theoretical expressions of $\nu_N\pm$ as a function of N (refs 2 3, 4 and 5) which were derived from the frequencies $\nu_N\pm$ which had been measured for many values of N (refs 4, 6, 7, 8 and 9) According to the formula given by Miller and Townes, $\nu_{27^-} = 53{,}070$ Mc /s

Measurements of vertical atmospheric absorption in the vicinity of 53,070 Mc /s have been made with a Dicke radiometer which had an input band-width of 1 Mc /s , an intermediate frequency of 60 Mc /s and an output integrating time of 25 sec The resulting curves of solar radiation received, I_s, versus frequency are shown in Figs 1, 2 and 3 The abscissæ show the local oscillator frequency as well as the two radio-frequencies received simultaneously by the radiometer The local oscillator frequency was measured by beating it with the sixth harmonic of an X-band stalo which, in turn, was checked periodically with a harmonic of a 100-Mc frequency standard In order to cancel radiometer and atmospheric low-frequency noise, the points shown were obtained by alternately pointing the radiotelescope antenna on and off the Sun and subtracting from an 'on-reading' the average value of the two adjacent 'off-readings'

Fig 1 shows the results obtained on September 29, 1961, where a strong absorption is evident near $\nu = 53{,}070$ Mc /s This frequency is marked ν_{27^-} on all the figures The results in Fig 2, taken on October 11, 1961, show no definite absorption at ν_{27^-}, but an absorption does appear at ν_{27^-} in the data of October 19, 1961, shown in Fig 3 The centre frequency of the absorption of Fig 3 agrees within experimental error with the value of ν_{27^-} calculated from the formula of Miller and Townes Fig 5 shows the results taken at a frequency away from ν_{27^-} on September 5, 1961, and is presented for comparison with the other figures

As shown in the figures, the points were taken during different times of the day, and consequently different lengths of atmosphere attenuated the Sun's radiation That the resulting differences in atmospheric transmission do not account for the changes of oxygen absorption shown on the three curves can be seen from Fig 1, where the four X's are points taken in succession after the highest frequency point was taken The Sun was lower in the sky, yet the radiometer readings are higher and show a definite frequency-dependent absorption which is absent from the points of Fig 2 Fig 4 shows the points taken during the 'off' portion of the radiotelescope on September 29, 1961 As ν_{27^-} is approached, the atmosphere becomes more absorbing and produces a higher antenna temperature Here too the X's are points taken in succession after the highest frequency point and corroborate the frequency dependent absorption shown in Fig 1

The graphs of Figs 6 and 7 showing zenith atmospheric molecular oxygen transmission as a function of radiometer local oscillator frequency are the results of calculations using oxygen-absorption formulæ[10,11] with the assumption of an isothermal atmosphere with an exponential decrease in pressure The intensity of the ν_{27^-} lines calculated for atmospheric

Figs 1, 2 and 3 show the intensity of solar radiation received, I_s, as a function of frequency The topmost numbers are the time of reception for the points denoted by dots Times for the points denoted by X's are given on the next to the topmost line All times are in E S T The units of I_s are arbitrary The antenna temperature of the higher points was approximately 70° K

temperatures of 280° K and 260° K is of the same magnitude as the measured intensity shown in Fig 3 Further calculations showed that if the temperature of the atmosphere were 260° K up to a height of 30 km and 240° K above 30 km, the ν_{27}- line of Fig 7 would not be detectable by the radiotelescope used in the experiments described here

It appears that the temperature of the high atmosphere, to which the peak of the oxygen line is sensitive, may vary enough over different days to produce the changes of oxygen absorption which have been measured Further experiments are being set up to study the ν_{27}- line and other oxygen telluric lines to learn how the intensity of oxygen absorption varies with time and to correlate this variation with other atmospheric variations so that the molecular oxygen line may be used to measure atmospheric conditions such as temperature and pressure

I thank Prof J Charney and Prof C H Townes for their helpful discussions on the temperature variations of the high atmosphere and the resulting effects on oxygen absorption I wish to acknowledge the advice and encouragement that I have received throughout the research from Prof Townes, who initially suggested to me the study of the oxygen telluric millimetre wave spectrum

FUSION OF SOIL DURING METEORITE IMPACT, AND THE CHEMICAL COMPOSITION OF TEKTITES

By Dr S R. TAYLOR

Department of Geophysics, Institute of Advanced Studies, Australian National University, Canberra

A RECENT proposal by Schwarcz[1] that tektites originate by fusion of soil at meteoritic impact sites raises several interesting issues A principal conclusion is that a mixture of soil and 3 5 per cent of the silicate phase of chondrites is close to the chemical composition of tektites

There are some well-known difficulties in matching the composition of tektites to that of common crustal materials, the major problem being to provide about 2 per cent magnesium oxide (about four times that of crustal material of similar silica content) Cherry and Taylor[2] first suggested a mixing hypothesis to solve the enigma of high magnesia and silica contents A suitable match for the major elements was produced by mixing arkose (which combined a high silica content with a low alkali concentration) with 7 per cent of the silicate phase of chondrites (selected to represent the composition of non-volatile material in comets) When this was proposed, no modern determinations for such critical elements as nickel or chromium were available

Recent determinations of nickel in tektites have been published by Ehmann[3], and I[4] have made a study of the chemical composition of the australite group of tektites, with determinations of trace elements on 24 specimens, and of major elements on 17 specimens (by H B Wiik) Preliminary results have been published[5-7] The average nickel content of australites is 29 p p m , and the chromium average is 77 p p m These data place severe restrictions on the amount of admixture of meteoritic material during tektite formation, and it is the purpose of this article to list some of the difficulties inherent in the proposal by Schwarcz[1]

(1) Iron meteorites, with several per cent nickel, provide no magnesium, and embarrassing amounts of nickel if any mixing occurs The average chondrite contains 1 34 per cent nickel This is mainly contained in the metal phase It seems difficult to restrict mixing in of the silicate phase only Chao[15] has reported the presence of iron–nickel spherules in a philippinite, and this must be considered strong evidence for an impact origin The question of place of impact, and whether by meteorite, asteroid or comet, remains undecided In the present connexion, the inclusion of iron spherules seems to rule out the restriction made by Schwarcz[1] of using only the silicate phase of chondrites

(2) A calculation has been made of the effect of the addition of 3 5 per cent chondrite, and this is shown in Table 1 Column 1 gives the average composition of chondrites[4] and column 2 represents 3 5 per cent of column 1, or the amount added in the calculation of Schwarcz[1] to soil Column 3 gives the average composition of australites (24 specimens)[4] The first seven elements, silica, aluminium, iron, magnesium, calcium, sodium and potassium, are given in per cent, and the remainder in parts per million (p p m) A comparison of column 2 (the meteoritic contribution) with the australite average in column 3 shows that nickel is the outstanding anomaly, being too abundant by a factor of 15, if such an amount of chondrite is added to any other parent material Cobalt likewise would be over-abundant by a factor of two, while 100 per cent of the chromium content is added, and nearly 40 per cent of the phosphorus content of australites

Table 1 COMPARISON OF COMPOSITION OF CHONDRITES (COL 1) WITH AUSTRALITES (COL 3)

Column 2 represents 3 5 per cent of the chondrite composition By adding such an amount to tektite parent material, 470 p p m nickel, 77 p p m chromium and 28 p p m cobalt are added

(3) I[8] have recently considered the effect on tektite composition of an origin by meteoritic splash, using the new trace element data for australites[4,5] The australite composition indicates that the amount of admixture of material from iron meteorites cannot exceed about 0 03 per cent, or from chondrites, about 0 1 per cent Australites possess an embarrassing nickel/chromium ratio of about 1/3, compared with 2,000 for irons (about 35 if average amounts of troilite are present) and 6 for chondrites If the total amount of 29 p p m nickel is provided from chondritic sources, only 5 p p m chromium is added, leaving 72 p p m chromium to be derived from non-meteoritic sources Terrestrial material with 72 p p m chromium can be expected to contain about 25 p p m nickel, so that it is difficult to bring more than a small fraction of the nickel from the chondrite

The problem is not eased by recourse to the group of high nickel tektites from Java, southern Indo-

Table 2. CORRELATION COEFFICIENTS (r) AND LEVELS OF SIGNIFICANCE FOR MAGNESIUM OXIDE AND OTHER MAJOR CONSTITUENTS IN 17 AUSTRALITES[4]

	r	Level of significance
MgO–SiO_2	−0.973	>0.01
MgO–Al_2O_3	+0.887	>0.01
MgO–FeO	+0.767	0.04
MgO–Na_2O	+0.784	0.02
MgO–K_2O	+0.829	>0.01
MgO–TiO_2	+0.851	>0.01
MgO–CaO	+0.267	Not significant

china, Billiton and Borneo, which contain an average of 295 p.p.m. nickel and 375 p.p.m. chromium[9]. The high nickel content may readily be provided from meteoritic sources, but not the chromium. It must be regarded as a curious coincidence that those tektites high enough in nickel to make an origin by meteoritic impact reasonable are also notably rich in chromium.

(4) If most of the magnesium were contributed from a chondritic source, an inverse relation should exist between it, and constituents, such as potassium, drawn mainly from the soil[1]. In fact, magnesium shows a good positive correlation with the other major constituents[4,10,11]. Care must be used in interpreting correlations in a closed array[12,13] and "in small samples, a correlation must be very strong to be significant"[12]. The correlation coefficients and levels of significance for 17 analyses of australites by H. B. Wiik[4] between magnesium oxide and the other major constituents are given in Table 2. Except for calcium oxide, all correlations are significant at the 0.04 per cent level, and most are significant at less than 0.01 per cent. The negative correlation with silica, the lack of correlation with calcium oxide and the positive correlations with the other constituents have been interpreted as indicating a mixture of quartz and shale, with some calcite, as the most likely parent material[14]. This conclusion is strongly reinforced by the trace element data[4–7]. It may be noted that the correlation of magnesium and potassium in tektites is the reverse to that observed in igneous rocks of similar silica content (68–80 per cent) and it is the identical behaviour of these two contrasted elements which is of such significance for parent material of tektites.

(5) A terrestrial meteorite impact of sufficient energy to distribute tektites over an area of 2×10^6 sq. miles (for example, australite distribution) is unlikely to involve only the upper layer of soil. To account both for the wide distribution and the restrictions on admixture of meteorite material[8], a meteorite collision at close to the maximum velocity of 72 km sec^{-1} seems required. Such an event would produce an observable crater, and underlying rock, as well as soil, would be involved.

(6) The calculation of Schwarcz[1] results in an average of 1,300 p.p.m. phosphorus. From the analyses of H. B. Wiik[4], the average content of phosphorus in australites is 130 p.p.m., a factor of ten lower. This difference is probably significant, although the precision in the older analyses used by Schwarcz[1] may be poor at this level, where relative deviations between different analysts may be of the order of 50 per cent[16].

Table 3. COMPARISON OF COMPOSITION OF TEKTITES WITH LOESS

	1*	2*	3*
SiO_2	73.72	73.45	75.02
Al_2O_3	12.34	11.53	12.32

MgO	2.07	2.05	1.66
CaO	2.70	3.50	2.85
Na_2O	1.31	1.28	1.33
K_2O	2.36	2.28	2.89
P_2O_5	—	0.03	0.10
TiO_2	0.83	0.70	0.98
Σ	100.06	99.76	100.13

*1 Average composition of 85 tektites (ref. 1).
*2 Average of 17 australites (ref. 4).
*3 Average loess (ref. 18). Less volatile matter at 1,000° C.

The suggestion by Schwarcz is of value in directing attention to widespread surficial deposits as possible parent materials. I[4] have suggested that loess might be a likely source. The composition given in Table 3 is very close to tektites. Magnesium oxide is slightly low (1.66 per cent) compared with tektites (2.07 per cent), and this difference, although small, may be significant. Phosphorus is somewhat high as well, although much closer to tektites than the soil average used by Schwarcz[1]. In addition, sodium was determined by difference in the analyses quoted[18], and only semi-quantitative trace element data are available, so that rigorous comparisons with tektite composition are not possible until this is remedied. Loess is, however, very much closer in composition to tektites than other common terrestrial material[19], the use of which implies only surficial melting (without deep excavation of a crater) as envisaged by Urey's comet hypothesis[17].

PACKING OF BINARY MIXTURES OF SPHERES AND IRREGULAR PARTICLES

By Prof. S. YERAZUNIS, J. W. BARTLETT and A. H. NISSAN
Department of Chemical Engineering, Rensselaer Polytechnic Institute, Troy, New York

THE packing characteristics of binary mixtures of spheres and irregular particles have been explored during an investigation of the occurrence of 'critical points' in the drying of impervious particulate solids in random packing. Initial investigations with equal glass spheres, 0.05 mm in diameter, using a container-to-sphere aspect ratio of about 750, led to an estimate of a packing fraction of 0.636 which

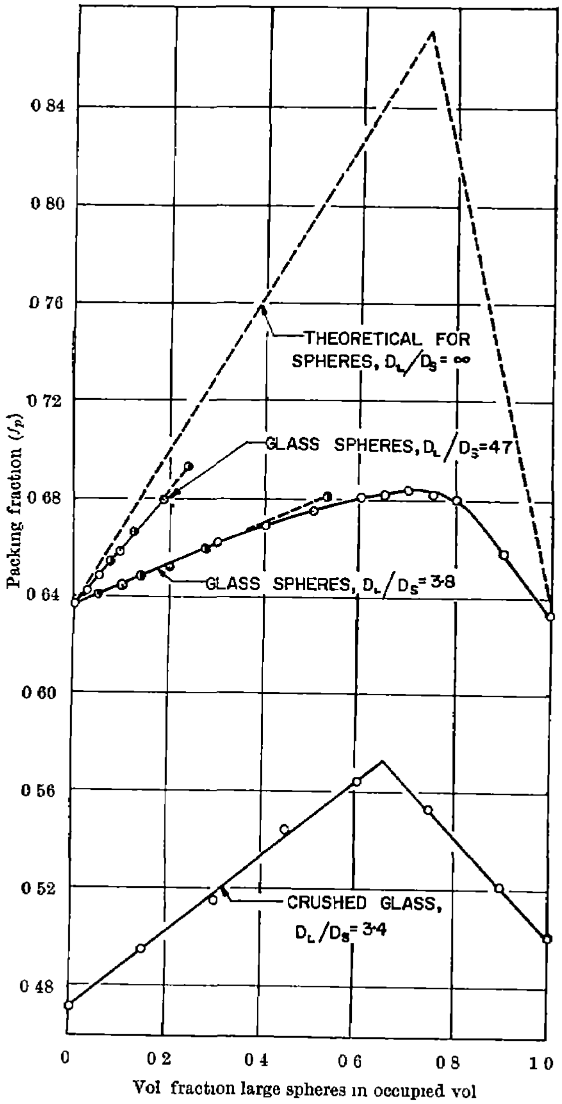

Fig 1 Packing fractions in binary mixtures ○, Experimental, ◑, theoretical using equation (4) with $K = 0 48$

compares favourably with Scott's[1] determination of 0 637 and Rutgers's[2] subsequent estimate of 0 641

The packing fraction of binary mixtures of spheres was found to be a function of the composition of the mixture and the ratio of sphere diameters The experimental results (Fig 1) for a diameter ratio of 3 8 show that a maximum value of the packing fraction of 0 684 is obtained at a composition of 0 735 volume fraction of large spheres in the occupied volume These results can be partly explained in terms of the theoretical behaviour of binary mixtures of an infinite diameter ratio In one extreme, the addition of a large sphere to a small sphere régime results in the replacement of small spheres producing an increase in the packing fraction by excluding the micro-voids associated with the small sphere régime which is replaced This replacement process may be continued only up to that point at which the large spheres are themselves arranged in dense random packing At the other extreme, small spheres can be added to an existing random array of large spheres, resulting in the partial filling of the existing voids This addition process may be continued until the macro-voids formed by the large spheres are entirely filled by small spheres in dense random packing For the case of spheres, the maximum packing fraction resulting from either the replacement or addition process will be $1 - (1-0\ 637)^2 = 0\ 868$ The packing fraction at intermediate compositions will be a linear function of composition for the infinite diameter ratio since both the small and large sphere régimes will correspond to infinite container-to-particle aspect ratios

For a finite diameter ratio, the distortion of the small sphere régime due to the large sphere surfaces must be taken into account An estimate of the effect can be obtained through the following arguments In the binary mixture, the small spheres can be imagined to occupy domains of size and shape determined by the number and the arrangement of the large spheres The average volume of the small sphere domains will be given by $(1 - V_LN_L)/N_L$, where V_L is the volume of the large sphere and N_L is the number of large spheres per unit volume of the mixture A characteristic length of the small sphere domain can be defined as D_D equal to $[(1 - V_LN_L)/(N_L)]^{1/3}$

The local aspect ratio, that is, particle-to-domain dimension, is approximately $[D_s][N_L/(1 - V_LN_L)]^{1/3}$, where D_s is the diameter of the small sphere

From Scott's measurements, the packing fraction of the small sphere domain, f_p^s, may be expressed in terms of the aspect ratio by

$$f_p^s = f_{p\infty} - KD_s[(N_L)/(1 - V_LN_L)]^{1/3} \qquad (1)$$

where $f_{p\infty}$ is the packing fraction for dense random packing of equal spheres in an infinite container and K is an empirically determined constant

Since the degree of distortion of the small sphere packing would be expected to be related to both the aspect ratio and the extent of the 'wall' (surface of the large sphere), equation (1) cannot be applied directly On the average each of the small sphere domains is associated with one large sphere It is proposed that an effective packing fraction f_{pe}^s be defined so as to reflect the area of the large sphere relative to a sphere of diameter corresponding to the characteristic domain length, D_D, that is, a function of $[D_L/D_D]^2$ The simplest assumption is to modify K in equation (1) as follows

$$f_{pe}^s = f_{p\infty} - KK'(D_L/D_s)^2D_s[(N_L)/(1 - V_LN_L)]^{1/3} \qquad (2)$$

where K' is a constant of proportionality which on further simplification can be absorbed in K Since the packing fraction for the mixture, f_p, is

$$f_p = V_LN_L + (1 - V_LN_L)f_{pe}^s \qquad (3)$$

it follows that

$$f_p = V_LN_L + [1 - V_LN_L]\left[f_{p\infty} - KD_sD_L^2\frac{N_L}{1 - V_LN_L}\right] \qquad (4)$$

In (4) K' was assumed unity, in other words, absorbed in K Theoretical packing fractions were calculated by (4) for the two sets of experimental data shown in Fig 1 (*a*) $D_s = 0\ 05$ mm, $D_L/D_s = 3\ 8$, and (*b*) $D_s = 0\ 13$ mm, $D_L/D_s = 47$ The constant, K, was originally estimated as 0 41 using Scott's[1] measurements for equal spheres in dimpled cylinders While the predicted and observed results were not in exact correspondence, the comparison was not unsatisfactory, a very good fit was obtained for K taken as 0 48 The correlation is excellent for the 3 8 diameter ratio up to a volume fraction of large spheres of 0 40

Above this concentration, it appears that the characteristic domain length is too small for equation (2) to represent the small sphere régime distortion adequately.

This analysis indicates that the mixture packing fraction for large sphere concentrations less than that corresponding to maximum compaction is determined by two opposing factors (*a*) the replacement of small sphere arrays and their associated microvoids by the large spheres; (*b*) the ensuing distortion of the residual small sphere domains determined by the characteristic length of the domain and the surface provided by the large spheres.

The compaction process for concentrations exceeding that associated with the maximum packing fraction has not been explained quantitatively for mixtures of finite diameter ratios. However, for the case of the 3·8 diameter ratio, it would appear to be a consequence of the distortion of the large sphere array due to the insertion of the smaller spheres. In this case, there exist very few voids in the random packed large sphere system capable of accommodating the smaller spheres. An expansion of the large sphere arrangement would be quite in order leading qualitatively to the observed behaviour.

Furnas[3] had previously inferred relations between the void fraction, size ratio, and composition of binary mixtures of broken solids. Although the experimental results presented in his and these investigations are in approximate agreement, the shape of the theoretical functions is dissimilar. Furnas's theoretical packing fraction curves are concave upwards in contrast to the predictions based on equation (4), which are very nearly linear. The discrepancy cannot be explained since Furnas did not report the basis for his theoretical curves.

Shown also in Fig. 1 are the packing fractions of mixtures of crushed glass particles. The material was obtained by crushing glass rod in a dry ball mill and sizing in a U.S. Standard Sieve Series. The resulting particles were highly irregular and of complex polyhedral shape; the nominal particle sizes were comparable with those of the spheres. The packing fraction of these mixtures followed the trends for spheres, suggesting that the irregular particles may be thought of as incomplete spheres. The maximum packing fraction occurred at a composition of 0·66 volume fraction occupied by the large particles, which compares favourably with the theoretical value of 0·68 based on the packing fractions of 0·50 and 0·47 determined experimentally for the large and small sizes, respectively.

INFLUENCE OF MECHANICAL AGITATION ON THE NUCLEATION OF SOME AQUEOUS SALT SOLUTIONS

By Dr. J. W. MULLIN and Dr. K. D. RAVEN

Department of Chemical Engineering, University College, London

NUCLEATION constitutes the first, and probably the least-understood, stage in the production of a new phase. Modern theories of nucleation stem from the work of Gibbs[1], Volmer[2] and others, who considered the conditions necessary for the equilibrium of a small spherical particle located within a larger mass of a different phase. This equilibrium, defined by the balance between surface tension and pressure forces, is an unstable one, since a slight increase or decrease in the size of the particle leads to indefinite growth or decay.

It is postulated by the Gibbs–Volmer theory that embryos of varying size occur within a metastable phase, and that any which exceed the critical equilibrium size grow spontaneously as particles of the new, stable phase. The energy, ΔG, required to form a critical nucleus can be calculated, and used in a general rate equation of the form

$$J = \nu \exp\left[-\Delta G/\mathbf{k}T\right]$$

Where J is the nucleation-rate, and ν is a constant for the system. This relationship leads to nucleation-rates in fair agreement with those obtained in practice.

Mechanical effects can profoundly influence the onset of nucleation, and as long ago as 1911, Young[3] and Berkeley[4] independently investigated the effect of mechanical shock on supersaturated aqueous systems. No systematic study of this aspect has been reported since their work, although several authors have referred to isolated investigations.

It is generally agreed that mechanical disturbances will enhance or even initiate nucleation, but no quantitative assessment of the effect has been made. However, during the course of some investigations made by the authors in a pilot-scale Oslo crystallizer, it became apparent that the relationship between agitation and nucleation was not a simple one. It was found that whereas nucleation was more prominent in disturbed than in quiescent systems, as generally supposed, an increase in the intensity of agitation did not necessarily lead to a continuous enhancement of the nucleation process.

A preliminary report[5] of this new phenomenon, which was investigated in more detail in a nucleation cell, was concerned only with ammonium dihydrogen phosphate solutions over a limited range of temperature. The work has now been extended to a number of other aqueous salt systems, and an explanation of the results is proposed.

The nucleation cell used for this work consisted of a 'Pyrex' glass beaker 60 mm. diameter × 80 mm. deep, equipped with a 1 × ¼ in. glass T-stirrer. A verticle 'Perspex' baffle, 10 mm. wide, protruded from the wall of the cell, and a thermometer placed diametrically opposite approximated to a second baffle.

Solutions were cooled at a constant rate in the cell at known agitation-rates and the temperature at

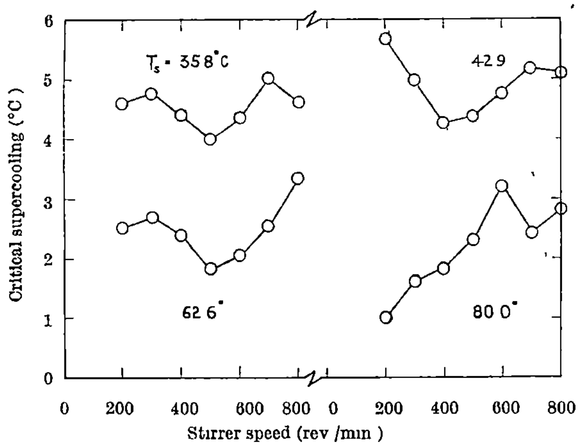

Fig. 1. Nucleation of ammonium dihydrogen phosphate solutions (T_s, saturation temperature)

which nuclei were first observed noted. Reproducible results could not be achieved unless the solutions were very carefully protected from inoculation by air-borne dust particles. A thick layer of liquid paraffin above the solution was found suitable for this purpose. The range of stirrer speed used was 200–800 rev./min., with a constant cooling-rate of 0.1° C./min. Nuclei were detected by visual observation, using oblique lighting, when they appeared as bright 'spangles'.

Some typical results obtained with aqueous solutions of ammonium dihydrogen phosphate are plotted in Fig. 1 as critical supercooling versus stirrer speed. By critical supercooling is meant the supercooling, in deg. C., below the saturation temperature, T_S, at which nucleation is first detectable. For saturation temperatures of about 40° C., increasing agitation at first reduces the supercooling required for nucleation, but further increase in agitation actually retards nucleation. Finally, at the highest usable rates of agitation, nucleation again increases.

At higher temperatures, the behaviour remains qualitatively the same, but the portion of the agitation range where increased agitation inhibits nucleation becomes larger until, at temperatures around 80° C., increased agitation inhibits nucleation throughout the agitation range available. (See also Fig. 3.)

It was not possible to determine nucleation temperatures accurately under quiescent conditions, but at all temperatures nucleation was much less pronounced in non-agitated than in agitated systems.

Data obtained from aqueous solutions of magnesium sulphate and sodium nitrate (Fig. 2) show that qualitatively their behaviour is similar to that of ammonium dihydrogen phosphate, but the temperature dependence of the relationship between nucleation and agitation is less clearly shown by sodium nitrate than by ammonium dihydrogen phosphate. It was not possible to draw any conclusions as to the influence of temperature on the nucleation behaviour of magnesium sulphate because temperatures were limited to below 45° C. to avoid transition to lower hydrates.

A few results have been plotted in Fig. 3 in terms of calculated values of critical supersaturation, rather than measured values of supercooling. Supersaturation is here defined as the ratio of the solution concentration to the equilibrium saturation concentration. Expressing the results in this way gives a more direct measure of the concentration driving force, and so of the speed at which nucleation and growth may be expected to proceed in different systems.

Nucleation is considered to occur by diffusion of solute particles to an embryo, followed by a pseudo-chemical reaction when the particle joins the lattice structure. The resultant dependence of the nucleation-rate, J, on agitation may be expressed by an equation of the form

$$J \propto (\text{rev./min.})^n$$

The index, n, should vary between zero, for conditions where the surface reaction step controlled the nucleation rate, and unity for a diffusion-controlled process. The fact that nucleation is more likely in agitated than in quiescent conditions has in the past led to the conclusion that nucleation is diffusion controlled. But the diffusional mechanism alone cannot account for the results reported here where increasing agitation is shown, under certain conditions, to reduce nucleation.

Experimental determinations of viscosity and diffusivity for saturated solutions of the salts used, at various temperatures, failed to reveal the existence of any

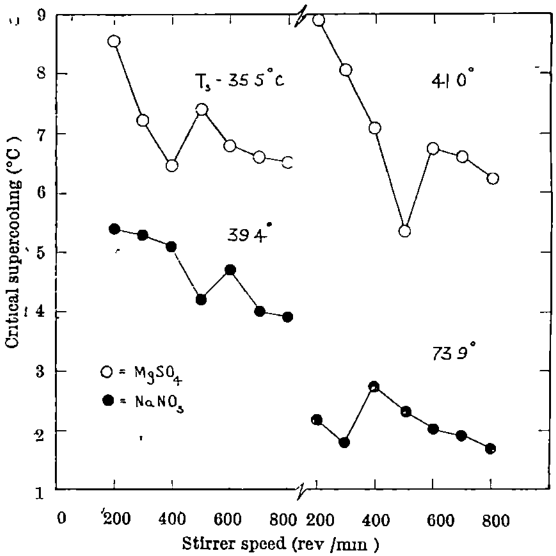

Fig. 2. Nucleation of solutions of magnesium sulphate and sodium nitrate (T_s, saturation temperature)

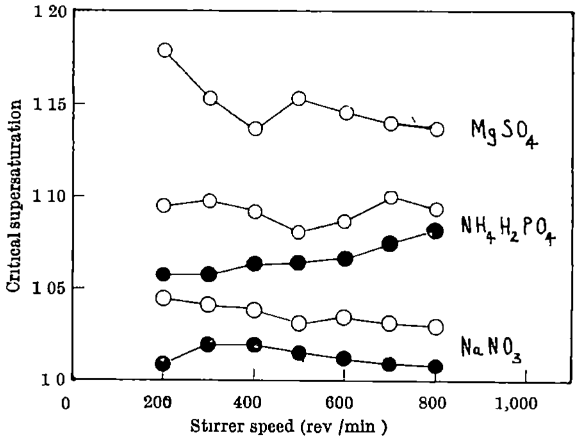

Fig. 3. Critical supersaturation versus stirrer speed: comparison of three aqueous salt systems. ○, T_s ~ 35° C.; ●, T_s ~ 70° C.

irregularities that could account for anomalous behaviour for a diffusional process.

Viscosities were determined in a standard Ostwald viscometer, immersed in a thermostat bath, and showed that viscosity was a smooth function of temperature for saturated solutions of each of the salts used. Viscosity was also a smooth function of temperature, for any given solution, showing no discontinuity at the saturation temperature. Diffusivities of saturated ammonium dihydrogen phosphate solutions were determined with a Zeiss diffusion interferometer; values varied smoothly from 3·38 to 4·81 × 10^{-6} cm^2/sec over the range 20–50° C.

Since these results offered no explanation of the nucleation effects reported here, other possible mechanisms that could inhibit nucleation were considered. It has frequently been suggested, and as often disputed, that attrition effects can operate between macro crystals in agitated crystallizers. The possibility that a similar disruptive effect, on a smaller scale, might be responsible for inhibiting nucleation was therefore considered.

On the macro-crystalline scale, attrition increases the nucleation process, as the broken fragments or disturbed surface nodules are generally of nucleic size. However, the fracture of nuclei, either by mutual collision, or impact with the vessel or stirrer, would yield fragments of less than nucleic size, and thus reduce the net rate at which embryos grow into nuclei.

At least two practical difficulties in the investigation of this latter possibility are immediately obvious. First, damage to true nuclei could not be studied as they are too small for any damage to be detected. Secondly, under the metastable conditions existing in supersaturated solutions, attrition effects would be masked by the normal growth and decay mechanisms operating. Accordingly, it was decided to investigate attrition among small macro crystals suspended in an inert medium, under the same agitation conditions as prevailed in the nucleation experiments.

Ways were considered for detecting damage to such crystals. Straightforward microscopic examination of a sample of the crystals before and after periods of agitation seemed possible, but to detect any but the severest of damage, the initial crystal mass would have to consist only of perfect, undamaged crystals, and the problems of producing quantities of such crystals of a small, fairly uniform size appeared formidable.

It was considered that damage arising from impacts between the stirrer and the crystals would be at least as serious as damage from inter-crystal collisions, and accordingly only the former effect need be studied. Furthermore, if the stirrer itself were of the same consistency as the crystals, it too would be damaged by such impacts, and this damage would be roughly equivalent to the total damage thereby suffered by the crystal mass.

A number of large single crystals were grown for use as stirrers in the following manner. A small needle crystal of ammonium dihydrogen phosphate was cemented to the end of a glass rod with epoxy resin to yield a miniature T-stirrer. This was left revolving gently in a slowly cooling saturated solution containing a stagnant mass of larger crystals to limit the supersaturation-level.

After cooling by about 8° C over a period of 24 hr., crystals grown in this way were approximately 1 in. long and ¼ × ¼ in. in cross-section, externally undamaged, and of almost perfect form, apart from slight asymmetry of the pyramidal ends occasioned by differing growth-rates due to the continuous rotation of the crystal in one direction.

The attrition experiments were conducted in the nucleation cell using one of these grown crystals in place of the stirrer, to which they approximated in size, to agitate a suspension of crushed ammonium dihydrogen phosphate crystals (< 40 mesh) in kerosene. Runs were conducted at various agitation-rates and for various times, and a qualitative assessment of the erosion of the leading edges of the stirrer crystal was made after each run by visual observation and photography.

The results showed that there was a threshold stirrer speed of about 400 rev./min., below which negligible attrition occurred. This threshold corresponded, roughly, to the degree of agitation at which inhibition of nucleation had first been noted. Attrition effects then increased markedly in extent up to the limit of the agitation range used (~ 1,000 rev./min.). No attrition of the crystal stirrer occurred when it was operated for prolonged periods of time in kerosene alone at the highest rate of revolution.

The nucleation experiments had shown that, at the higher available rates of agitation in the cell, increasing agitation resulted in an increased tendency to nucleate. To account for this reversion to 'conventional' nucleation behaviour would require an upper limit at which attrition reached a maximum, but this could not be demonstrated as no accurate measure of attrition was available.

However, the existence of the threshold suggested that attrition would not occur unless the impact velocity exceeded some minimum value sufficient to fracture the crystal lattice. The velocities of the embryos in an agitated system will not be uniform, but will have a spread which may be assumed to approximate to a Gaussian distribution. Accordingly, the probability of attrition occurring for any given impact depends on the probability of the impact velocity exceeding this minimum value.

A plot of mean particle speed against the proportion of particles having a speed in excess of some given value is, for a Gaussian distribution, given by an S-shaped cumulative distribution curve, or ogive. Since mean particle speed may be assumed to be proportional to stirrer speed, the relationship between attrition effects and stirrer speed should also follow an ogive relationship (Fig. 4b). The influence of agitation on diffusional and surface effects can be

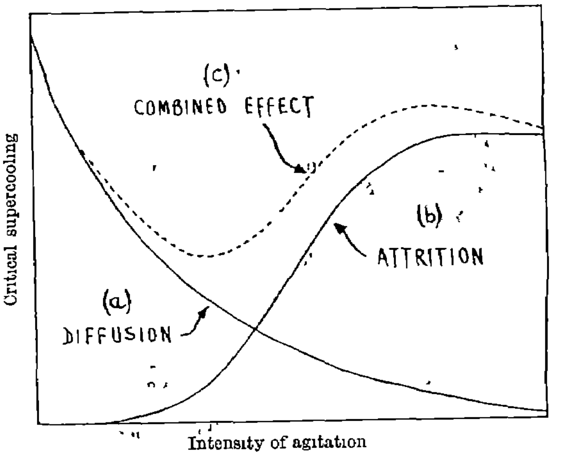

Fig. 4. Construction of a theoretical curve relating the intensity of agitation of a solution to its tendency to nucleate

predicted as described here, from a power law (Fig 4a). A combination of these two relationships yields a theoretical 'nucleation versus agitation' curve. While the relative magnitudes of the two conflicting effects cannot at present be predicted, the general form of this plot will be as shown in Fig 4c.

This composite plot may be compared with the experimental graphs shown in Figs 1 and 2. At low temperatures the agreement is quite good, but at higher temperatures the experimental plots tend to deviate from the theoretical curve. The prominence of nucleation inhibition at elevated temperatures may possibly be due to the thermal weakening of the metastable embryo lattices and the consequent lowering of their resistance to attrition.

A HYPOTHESIS CONCERNING THE WAY OF CODING INTERACTION BETWEEN TRANSFER RNA AND MESSENGER RNA AT THE LATER STAGES OF PROTEIN SYNTHESIS

By Dr Zh. A. MEDVEDEV

Department of Agrochemistry and Biochemistry, Timiriasev Agricultural Academy, Moscow, A 8, U S S R

IT has been shown during the past few years that the linking of activated amino-acids to the terminal adenosine of special low-molecular forms of so-called 'transfer' RNA (or *s*-RNA) is the preliminary stage of protein synthesis. Molecules of these 'transfer' RNA's carry the activated amino-acids to the ribosome particles where the amino-acid moieties are incorporated into newly forming peptide chains.

This interaction between 'transfer' RNA and ribosomal RNA has become a central point of some present hypotheses concerning the possible mechanism of reproduction of amino-acid sequences in proteins[1–8].

Though differing in some details, all these hypotheses have suggested that the polynucleotide chains of different molecules of 'transfer' RNA's, consisting of some 100 bases, are complementary (or have some restricted three-nucleotide complementary sequences) to the different parts of template RNA. It has been suggested, therefore, that among many collisions between 'transfer' RNA and ribosomes some can be effective in producing exact interaction between complementary nucleotide sequences and result in amino-acid transfer in accordance with the template 'code'[9].

However, the mechanism of protein synthesis now seems to be more complicated especially in the ribosomal stage. The discovery of a special RNA-messenger of genetic information which acts as a real informative template of protein synthesis[10–12], the finding that only a proportion (about 10 per cent) of 70 *S* double ribosomes are active as the sites of protein synthesis[13], and that the disintegration of these 'active' 70 *S* ribosomes into two particles stops protein synthesis which resumes after re-integration[14], and finally the interesting results demonstrating that such disintegration releases some polypeptides and peptides with high specific activity[15,16] (in experiments with amino-acids labelled with carbon-14) suggested the possibility that the amino-acids are incorporated in the 'active' 70 *S* ribosomes (containing the 'messenger' RNA as activator) in the groove between 30 *S* and 50 *S* particles[13].

In addition, the finding in cells of special so-called 'transfer' enzymes responsible for the transfer of *s*-RNA–amino-acid complexes to ribosomes[17–20] makes it somewhat difficult to explain the interaction between this *s*-RNA and the template on the basis of random collision only. If one takes into consideration that 'transfer' RNA is used repeatedly for protein synthesis without intermediate breakdown[21], that its 100 nucleotide strand is enriched by 'unusual' additional nucleotides, especially pseudo-uridine[22–25], and that the 'messenger' RNA consists of some 1,000 bases, then it becomes clear that all these data have to be considered in any coding speculations concerning the transfer of information from DNA and RNA to direct protein synthesis.

The recent achievements in the experimental attack on the coding problem[26–33] must be discussed, of course, not only from theoretical or statistical points of view. when the nucleotide code for amino-acids becomes a reality it must be considered as part of the complicated system of protein synthesis.

The following general characteristics of the amino-acid code seems now to be the best-established as a result of new experiments: (*a*) The code has a triplet nature (three nucleotides code one amino-acid). (*b*) The code is of the non-overlapping type. (*c*) The code is degenerate and one amino-acid can be coded by several triplets of bases.

But though these suggestions in the genetic code are now widely known, one can see that the evidence which supports them is indirect and some other speculations on the nature of the code are still possible.

Here we have devised an overlapping type of code which can explain the facts concerning the mutants of tobacco mosaic virus which have been used as the main argument for the existence of non-overlapping coding triplets[32,33]. The non-overlapping code was deduced from the fact that the alteration of a single nucleotide leads, as a rule, to the alteration of a single amino-acid, though if the code is overlapping the same alteration would produce a change in two or three adjacent amino-acids in the polypeptide chain.

But if one suggests that the coding nucleotide triplets are composed of non-adjacent nucleotides in the template and the transfer RNA, then the same result of mutation could be explained in the case of

Fig 1. Outline of different possible coding interaction between transfer RNA–amino-acid–transfer enzyme complex and messenger RNA as a template

an overlapping code, if the complete length of polypeptide chain is not bigger than the two or three lengths of transfer RNA Alternatively, the specific nucleotide triplets may be located not far from the terminal position (Fig 1) If only three adjacent nucleotides are necessary for coding, it would be difficult to understand the role of so long a polynucleotide of transfer RNA (80–120 nucleotides) To solve this difficulty some possibilities have been suggested concerning the mechanism of the elimination of the main part of transfer RNA polynucleotide chain from binding with the template (breakdown of transfer RNA before binding[2,4], formation of the protein along a microsomal phospholipid membrane[7] sited at a distance equal to the length of transfer RNA chain next to the triplet coding sequence and at the end of the chain and some others)

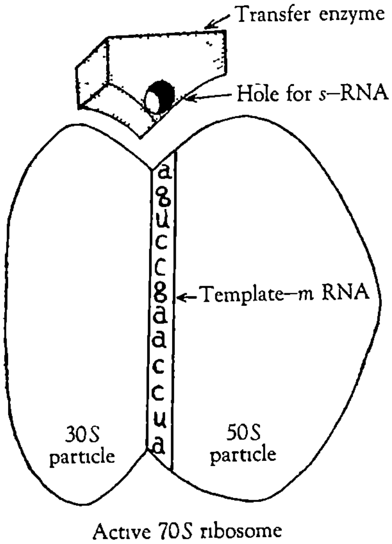

Fig 2 Outline of interaction between 'transfer' enzyme and 70 S ribosomes

In my model of the later stages of protein synthesis a new possibility of such elimination is suggested—the masking of the greater part of the transfer RNA chain by its entering into a hole or groove in the transfer enzyme molecule (some analogy with the location of RNA in an intact virus particle) I think that the pseudo-uridine nucleotide can probably serve for the necessary fixation of the polynucleotide chain position in the hole Fig 2 shows a possible mode of interaction between transfer enzyme, 70 *S* ribosome and messenger RNA

I favour the idea of this overlapping code not because it seems to be more economical, but because it can better explain the parallelism of distances between nucleotides and amino-acid residues and because the deletion or addition of a single nucleotide means in this case a point mutation only, but not the wrong reading of all the genetic information and the production of completely nonsense protein molecules

I thank Dr P N Campbell, Dr M B Hoagland and Dr G Webster for useful discussion of my suggestions before publication

VISUAL PIGMENT 544, A PRESUMPTIVE CONE PIGMENT FROM THE RETINA OF THE PIGEON

By Dr C. D B. BRIDGES

Visual Research Division, Ophthalmological Research Unit (Medical Research Council),
Institute of Ophthalmology, London, W C I

ALTHOUGH iodopsin has so far been extracted only from the retina of the chicken, it has been held to be the mediator of photopic vision in a number of vertebrates Thus, Wald, Brown and Smith[1] have written " it seems probable that it is the major pigment of cone vision in the frog, snake and cat" This view has arisen because of a resemblance between the photopic sensitivity curves for these animals and the extinction of iodopsin This resemblance, however, does not extend to the photopic sensitivity[2] of the chicken, which is maximal some 20–30 mμ higher than the extinction maximum of iodopsin (562 mμ) This discrepancy is often considered to be due to the filtering action of the coloured oil-droplets in the cones In recent years the extinction spectrum of iodopsin has been compared not with the photopic sensitivity of the chicken, but with the more widely studied and more accurately known function for the pigeon With the view of determining whether this comparison is justified on the basis of the pigeon's visual pigments, I have prepared extracts of photosensitive material from the retinæ of dark-adapted pigeons, these extracts have been analysed by the method of partial bleaching[3]

Owing to the kind assistance of the Medical Officer of Health for Westminster, pigeons which had been trapped alive for the purposes of pest control were dark-adapted overnight and were then killed by breaking their necks in darkness The dead birds were brought to this laboratory in a light-tight bag Within 1½–3 hr of death the whole retinæ together with the adhering pigment epithelium had been removed under normal dark-room conditions The subsequent procedure was similar to that described by Wald, Brown and Smith[1] for their chicken extracts The retinæ from 18–25 birds were shaken with 50 per cent w/v sucrose in McIlvaine's *p*H 7 0 buffer, centrifuged at 4,000 relative centrifugal force, and the resulting supernatant suspension of photoreceptors was then precipitated by dilution with McIlvaine's *p*H 7 0 buffer and centrifuging at 35,000 relative centrifugal force After washing once with distilled water (*p*H 6 6) the precipitated material was freeze-dried and extracted five times with petroleum ether, b p 60°–80° These extracts contained the yellow colouring materials of the oil-droplets Residual traces of petroleum ether were pumped off and the dried residue was extracted for about 17 hr at 4° C with 4 per cent digitonin in McIlvaine's *p*H 6 6 buffer

The curve describing the filled circles in the upper part of Fig 1 is the extinction spectrum of an extract prepared in this manner The remaining spectra were obtained during the course of an experiment, typical of the series, designed to test the homogeneity of the extracted photosensitive material The spectrum represented by the dotted curve in Fig 1 was measured after 45 min exposure to deep red light of dominant wave-length 720 mμ and that by the dashed curve after 25 min exposure to light of wave-length 620 mμ A subsequent identical exposure to λ720 mμ light produced no further change of extinction but when the solution was exposed to white light the spectrum altered to that shown by the open circles The two difference spectra representing extinction changes due to the initial deep red and final white irradiations are shown in the lower half of Fig 1 Clearly the solution contains two photosensitive pigments, for the material bleached by red light has a maximum loss of extinction at about 545 mμ (difference spectrum shown by the crosses), whereas the loss of extinction caused by the final white irradiation was maximal at 505 mμ (difference spectrum shown by the open circles)

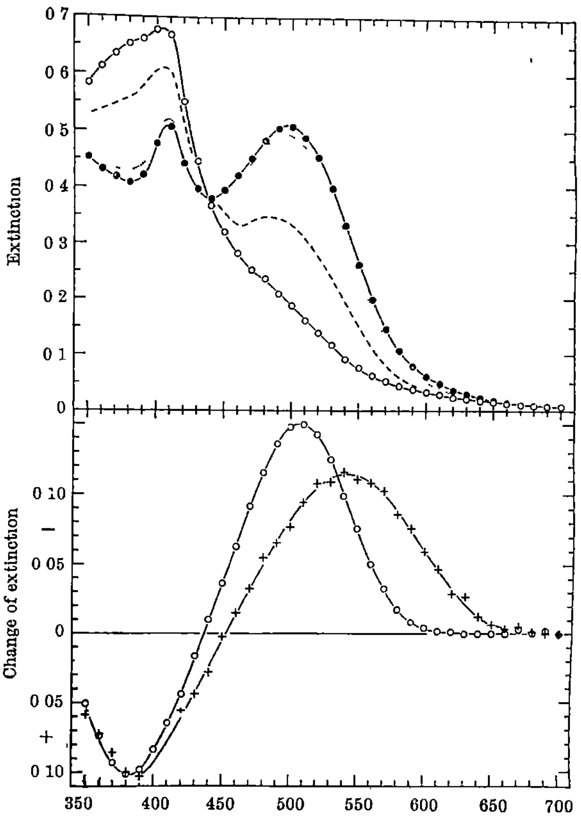

Fig 1 A typical experiment designed to test the homogeneity of pigeon visual pigment Upper half ●, initial spectrum, , after 45 min exposure to λ 720 mμ light (from a Unicam *SP* 500 monochromator, exit slit at 1 0 mm, Ilford filter No 206) ––––, after 25 min exposure to λ 620 mμ light (exit slit at 0 6 mm Ilford filter No 204), a subsequent exposure to λ 720 mμ (identical with the first one) produced no appreciable change of extinction, ○, after 10 min exposure to white light (from a 15-W lamp) Lower half +, difference spectrum due to the initial λ 720 mμ irradiation (×5), ○, difference spectrum due to the final white irradiation *p*H 6 6, all extinction spectra measured at 25 ± 2° C on a Unicam *SP* 500 spectrophotometer, extinctions refer to a 1-cm optical path

In all the experiments carried out, it was found that the photo-sensitive pigment remaining after exhaustively irradiating the solutions with red light yielded identical difference spectra with λ_{max} at 504–505 mμ. From 490 to 620 mμ these difference spectra were identical with the extinction spectrum of visual pigment 502 (ref. 4), and it is therefore concluded that one of the pigeon pigments is a rhodopsin with λ_{max} at 502 mμ. The same pigment has been extracted from the retina of the domestic duck (my own observation).

What is the λ_{max} of the red-sensitive pigment? In view of Wald's[5] reference to some unpublished work of Brown in which she had "extracted iodopsin from the pigeon retina" and found it had "virtually the same spectrum as chicken iodopsin", it was at first thought possible that the difference spectrum maximal at 545 mμ merely represented a mixture of iodopsin, λ_{max} 562 mμ, contaminated by the bleaching of some of the large excess of rhodopsin present. In order to test this assumption, it was necessary to obtain the rhodopsin free from the red-sensitive pigment and then see what proportion of this rhodopsin could be bleached by an identical red irradiation. The results of such an experiment are illustrated in Fig. 2. The solution was first irradiated for 1 hr with 720 mμ light. The difference spectrum for this operation (open circles) has λ_{max} at 544 mμ and ΔD_{max} of 0.0483. All the red-sensitive pigment was then removed by irradiation with light of wave-length 620 mμ. This operation left about 60 per cent of the estimated initial amount of rhodopsin. A second deep-red irradiation identical in all respects with the first caused no detectable bleaching, only a slight rise of extinction amounting to 0.0030, probably unconnected with the irradiating light, was observed. This is shown by the dashed curve in Fig. 2. Since the light which produced the initially observed difference spectrum was incapable of bleaching any of the rhodopsin present it must be concluded that this represents the true difference spectrum of the red-sensitive pigment. Similarly, in none of the experiments carried out was it possible to find any evidence that bleaching operations which yielded difference spectra maximal at 540–546 mμ had caused any concomitant rhodopsin bleaching.

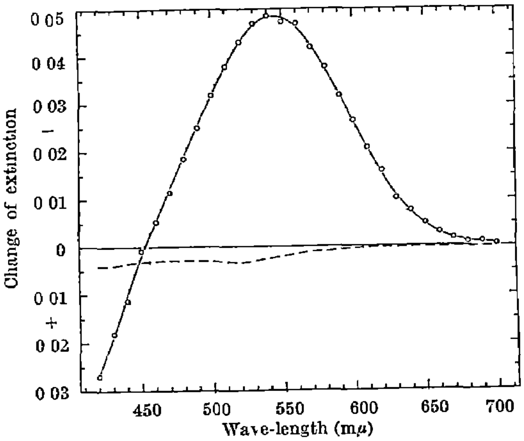

Fig. 2. Experiment showing that the red-sensitive difference spectrum represents the bleaching of a pure pigment, and is not contaminated by any concomitant rhodopsin bleaching. o, difference spectrum due to an initial exposure of 1 hr to λ 720 mμ light (exit slit at 1.0 mm, Ilford filter No. 206). The red-sensitive material was then removed by irradiation with λ 620 mμ light, and the solution was again exposed to an irradiation identical in all respects to the first. The difference spectrum shown by – – – – gives the change in extinction due to this irradiation. *p*H 6.3, other details as for Fig. 1

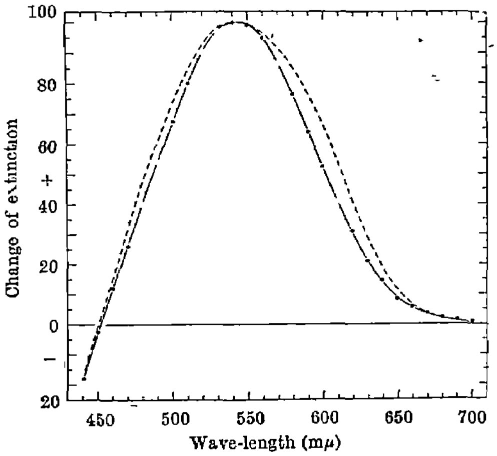

Fig. 3. An attempt at simulating the difference spectrum of the red-sensitive pigment by adding the difference spectra of pigeon rhodopsin and chicken iodopsin. – – – –, the summed difference spectra of pigeon rhodopsin (1 part) and chicken iodopsin (2.3 parts); ●, difference spectrum of the red-sensitive pigment (mean of five results on three separate extracts)

In any event, it is not possible to simulate the difference spectrum of the red-sensitive material by adding together the difference spectra of pigeon rhodopsin and chicken iodopsin. In Fig. 3 an attempt has been made to do this: the dashed curve represents the summed difference spectra of these two pigments (one part of rhodopsin to 2.3 parts of iodopsin), while the filled circles represent the red-sensitive difference spectrum. Although the λ_{max} of these two curves are both 544 mμ, the composite difference spectrum is obviously much too broad to fit the experimental results.

Further evidence that the red-sensitive component is a single pigment is provided by considering the shape of its extinction spectrum. This has been derived in the same manner as that used by Wald, Brown and Smith[1] for iodopsin. A difference spectrum represents the difference in extinction between a visual pigment and its photoproducts: in the present case, at *p*H 6.6, these photoproducts are probably retinene and the protein moiety of the visual pigment molecule. If the extinction spectrum of this mixture were known, then by adding it to the observed difference spectrum the extinction spectrum of the visual pigment should result. Wald, Brown and Smith[1] have published the spectrum of a mixture of retinene and the protein moiety of chicken iodopsin (at a *p*H of 6.5), and in the absence of data corresponding to the present investigation, this has been used to derive the extinction spectrum shown in Fig. 4. The figure shows that the extinction spectrum of the red-sensitive component is the same as that for a hypothetical pigment, with the same λ_{max} of 544 mμ, derived from Dartnall's nomogram[4]. This agreement would be impossible if a mixture of rhodopsin and iodopsin were used instead of the experimental results.

These considerations show beyond reasonable doubt that the second pigment of the pigeon retina is not chicken iodopsin but is a new pigment with λ_{max} at 544 ± 3 mμ (visual pigment 544). In conformity with every known visual pigment, its extinction spectrum is in agreement with that predicted by Dartnall's nomogram. In view of this conclusion, Wald's[5] reference to the extraction of iodopsin from the pigeon retina is puzzling. Visual pigment 544 only accounts for 15 per cent of the total photopigment, and a possible explanation would be

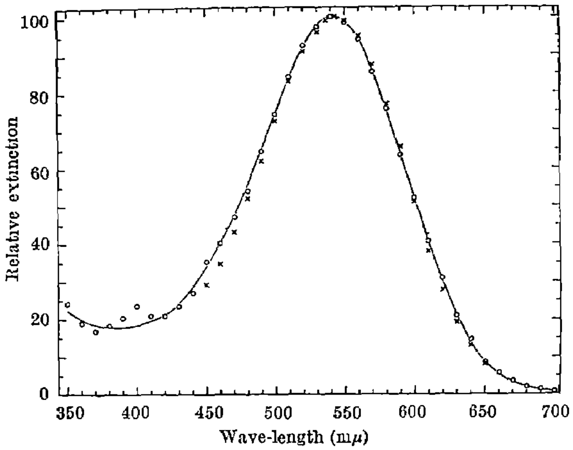

Fig. 4. Extinction spectrum of the red-sensitive pigment. O, extinction spectrum of the red-sensitive pigment (calculated as described in the text); ×, visual pigment 544 according to Dartnall's nomogram

that the results were similar to those reported here, but that the difference spectra obtained by exposure to deep-red light were regarded as a mixture of rhodopsin and iodopsin. Further discussion of this discrepancy must be deferred until Mrs. Brown's results have been published.

Is it possible to determine whether visual pigment 544 is a rod or a cone pigment? In one experiment concerning this question, each isolated retina was very gently stirred in a tube of 0.9 per cent saline prior to placing in the sucrose solution. It was thus hoped that the more fragile cone outer segments would be washed into the saline, leaving the retina relatively cone-free. A digitonin extract from the retina was prepared as previously described. The saline, which to the naked eye contained a number of detached pieces of pigment epithelium, was centrifuged and the precipitated material was dried and extracted first with petroleum ether, finally with digitonin. Analysis of the photosensitive material in each digitonin extract revealed that tissues which contained 82 per cent of the total retinal visual pigment 544 had been washed into the saline. Only about half (52 per cent) the total retinal rhodopsin was found in the 'saline' fraction.

This experiment shows, therefore, that visual pigment 544 is present in receptors which are more fragile or more deeply embedded in the pigment epithelium than those which contain the rhodopsin, and consequently the results suggest that visual pigment 544 is a pigment primarily of the cones.

The discovery that the pigeon has a visual pigment some 18 mμ below that of chicken iodopsin raises a number of questions concerning the interpretation of spectral sensitivity curves. It is proposed to consider these in a paper to be published shortly[6].

ACTION OF 7,12-DIMETHYLBENZ(ALPHA)ANTHRACENE ON THE MITOTIC ACTIVITY OF NORMAL AND MALIGNANT RAT FIBROBLASTS *IN VITRO*

By V. B. STARIKOVA and J. M. VASILIEV

Institute of Experimental and Clinical Oncology, Moscow, U.S.S.R.

CARCINOGENIC hydrocarbons as well as some other carcinogenic agents (for example, ionizing radiation) can inhibit the growth of various normal and neoplastic tissues both *in vivo* and *in vitro*$^{1-3}$. For the better understanding of mechanisms of chemical carcinogenesis it is important to know whether the sensitivity of cells toward the growth-inhibiting action of these hydrocarbons is changed in the course of neoplastic transformation.

The aim of our experiments was to examine the sensitivity of the primary cultures of normal rat connective tissue and of rat sarcomas to the action of very strong carcinogenic hydrocarbon-7,12-dimethylbenz(α)anthracene (DMBA).

Three types of normal connective tissue were used in these experiments: (1) Granulation tissue developed in adult rats around subcutaneously implanted 'Cellophane' films, the specimens of tissue were taken for cultivation 14 days after the implantation of films. (2) Subcutaneous connective tissue of rat embryos about 18–20 days after gestation. (3) Heart fibroblasts of rat embryos.

Only primary induced tumours were used in the experiments with neoplastic tissue.

Two types of sarcomas were tested: (1) Those induced by DMBA implanted in pellet form subcutaneously, each pellet contained 1 mgm. of hydrocarbon, tumours usually formed 4.5–6 months after the implantation of pellets. (2) Those induced in the rat connective tissue by subcutaneously implanted 'Cellophane' films. Tumours usually formed 10–16 months after the implantation of films (see ref. 4 for details of method). Each of the normal and malignant tissue types was used in five separate experiments. Tissue specimens in each experiment were taken from a new animal.

Thus, ten various induced sarcomas were used in all experiments, histologically all these tumours were fibrosarcomas and pleomorphic-cell sarcomas.

Tissue fragments were cultivated on the plasma clot in Carrel flasks in the synthetic medium 199 supplemented with 10 per cent calf serum. DMBA was dissolved in acetone and then added to the culture fluid medium so that fine suspension of the hydrocarbon was formed. Control experiments showed that even the highest concentration of acetone added to the medium in our experiments (1 per cent) did not change the mitotic activity of the cultures. Various concentrations of DMBA (ranging from 0.25 to 0.000025 mgm. per ml. of medium) were added to the various groups of explants in each experiment. The minimal number of explants in

Table 1. INFLUENCE OF DMBA ON THE MITOTIC ACTIVITY OF THE PRIMARY CULTURES OF NORMAL RAT CONNECTIVE TISSUES

each group was 12. DMBA was present in the medium during the period of cultivation. Seven days after the explantation all the cultures were fixed in Schabadasch mixture[5] and then stained with Meyer's hæmatoxylin. The number of mitoses per 1,000 cells was counted in five various explants of each group. The statistical significance of the differences between average mitotic indices in various groups was tested by the 'Student' Fisher small-sample method. Average culture areas in various groups were also compared. Morphological examination showed that all the normal and neoplastic tissues tested in these experiments gave the outgrowth of cells of fibroblastic type.

Results of experiments are summarized in Tables 1 and 2. As can be seen (Table 1) DMBA in all the concentrations caused severe inhibition of the growth of normal fibroblasts. High concentrations of DMBA prevented completely the outgrowth of the normal cells from the explanted fragments; smaller concentrations of the same hydrocarbon reduced the mitotic activity several times as compared with that of control cultures. DMBA did not cause any characteristic changes in the distribution of relative frequencies of various mitotic phases in the cultures.

Other results were obtained in the experiments with the explants of induced sarcomas. In most of these experiments only the highest concentration of DMBA (0·25 mgm./ml.) caused partial or complete inhibition of mitotic activity; in two experiments even this concentration did not reduce the mitotic activity. Smaller concentrations of DMBA did not cause any statistically significant inhibition of the mitotic activity in the cultures of most sarcomas. In some groups where DMBA was added average mitotic indices were even somewhat higher than those in corresponding control groups.

The changes of the average explant areas caused by DMBA in different groups were in general similar to the changes of the average mitotic activity described here.

Thus, in the *in vitro* experiments normal fibroblasts of rat embryos and of adult rats proved to be much more sensitive to the growth-inhibiting action of DMBA than the cells of rat sarcomas. High resistance of the primary induced sarcomas to the growth-inhibiting action of carcinogenic hydrocarbons was observed by Haddow[6] in the experiments *in vivo*. All these facts are in good agreement with the suggestion that formation of a new cell type resistant to the toxic action of carcinogen occurs in the course of chemical carcinogenesis[1]. It is interesting that increased resistance to DMBA was observed not only in the experiments with the cultures of sarcomas induced by the same hydrocarbon but also in the experiments with rat sarcomas induced by the essentially different carcinogenic agent, that is, by 'Cellophane' film. This observation supports the suggestion concerning the similarity of processes which are induced in the subcutaneous tissue of rats by carcinogenic hydrocarbons and by 'Cellophane' films, and which lead to the development of sarcoma[7]. Further work is necessary to elucidate the mechanism of the increased resistance of sarcomatous cells to DMBA and to discover the role of the phenomenon in tumour development.

DELETIONS OF ALLOTYPIC γ-GLOBULINS IN ANTIBODIES

By PROF. P. G. H. GELL and DR. A. KELUS

Department of Experimental Pathology, University of Birmingham

MANY attempts have been made to demonstrate structural or chemical differences between antibodies and 'normal' γ-globulins. Recently, Edelman *et al.*[1] have shown that anti-hapten antibodies in guinea pigs—antibodies, that is, directed against a single definable determinant group, in contrast with the manifold determinant groups reacting with antiprotein antibodies—give an individual and characteristic pattern on starch-urea electrophoresis. They were unable to demonstrate this phenomenon with rabbit antibodies. It seemed nevertheless possible that, if indeed antigens selectively stimulate γ-globulin antibodies of a particular structure, some rabbit antibodies might show signs of such selection. A useful 'marker' for such differences between γ-globulin molecules in a single serum is the 'allotype' (a genetically determined group on the molecule demonstrable by means of antisera raised in animals of the same species lacking that allotype[2–4]) since there is reason to suppose that individual molecules in the serum of an animal of heterogeneous allotype (for example, *ADEF* in the notation of Dubiski and Kelus[5]) vary in the particular allotypic marker which they carry. It seemed possible that as a result of the selectivity of the antigenic stimulus, antibody molecules might lack some of the allotypes present in the total γ-globulin from the same animal.

We have prepared antigen–antibody precipitates from the sera of individual immunized rabbits, and examined the redissolved precipitates for the presence of all the allotypes known to occur in the original serum. Twelve antisera from single rabbits were available. Of these, six (Nos. 1–6) were directed against haptenized ovalbumin: they contained antibodies reacting with normal ovalbumin, and also antibodies reacting with conjugates of the appropriate hapten on a non-cross-reacting protein (guinea pig albumin): the specific precipitates from both systems were examined. One antiserum (No. 7) was raised against bovine seralbumin: the antibodies cross-reacting with sheep seralbumin were first separated, and then the more bovine seralbumin-specific antibodies thrown down by reacting the supernatant with bovine serum albumin. One antiserum (No. 8) against *Streptococcus pneumoniae* Type III carbohydrate was also examined. All the precipitates were made at the equivalence point or at slight antibody excess, and redissolved in excess of antigen, or of free hapten, where that was applicable. Solution of precipitates was complete in the latter and almost complete in the former case. Four antisera against sheep cells (Nos. 9–12) were tested by coating sheep-cells with a sub-agglutinating dose of the antiserum, washing, and agglutinating the coated cells with each of the allotypic antisera, on the principle of the antiglobulin test.

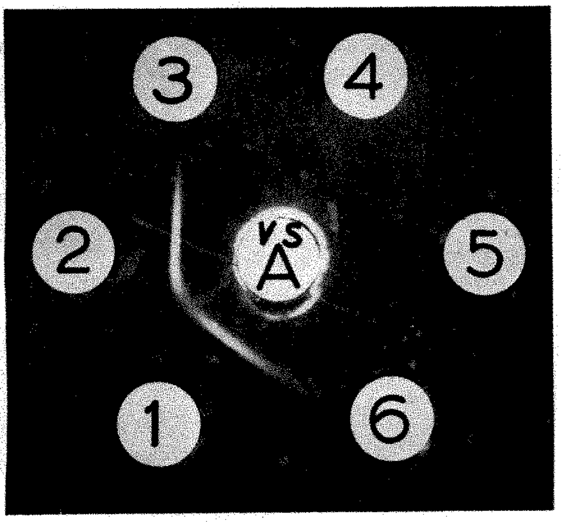

Fig. 1. Reactions with anti-*A* antiserum: 1, rabbit No. 1, whole serum; 2, rabbit No. 1, ovalbumin precipitate redissolved in ovalbumin; 3, ovalbumin; 4, conjugate, *p*-COOH-phenyl NCS guinea pig albumin; 5, free hapten, sodium *p*-amino-benzoate; 6, rabbit No. 1, conjugate precipitate redissolved in free hapten (5)

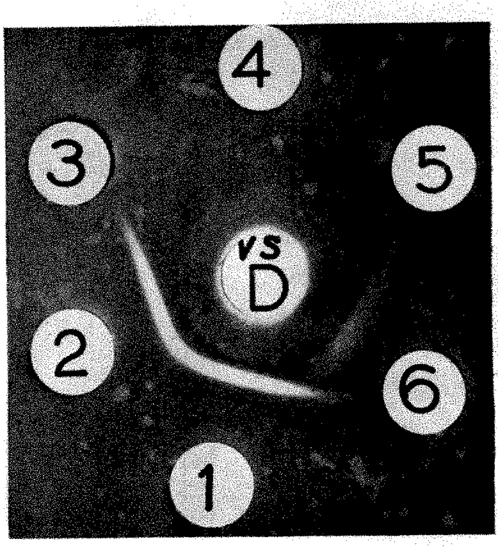

Fig. 2. Reactions with anti-*D* antiserum. For description see Fig. 1

The anti-allotype antisera available were against *A*, *B*, *C*, *D*, *E*, *F* (Dubiski and Kelus[5], and personal communication). Ten of the rabbits were found to be of allotype *DF*, the commonest among English laboratory stock. In all cases, both these allotypes were readily demonstrable in the precipitates (Nos. 2–7) or attached to the cells (9–12). One rabbit (No. 8: immunized to *Streptococcus pneumoniae*, Type III) was allotype *BDF*, and similarly all three allotypes were demonstrable in the antibody redissolved in excess of polysaccharide Type III.

One rabbit (No. 1) was apparently heterozygous at the *A* locus and at the *D* locus, being *ADEF* (*A* and *F*, *D* and *E* appear to be determined by allelic genes). The precipitate with ovalbumin from the serum of this animal, redissolved in ovalbumin,

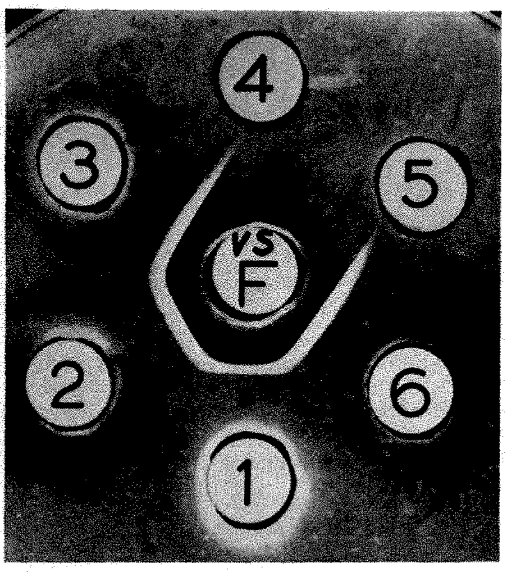

Fig. 3. Reactions with anti-*F* antiserum. 1, Rabbit No. 1, conjugate precipitate redissolved in free hapten (5); 2, rabbit No. 1, supernatant serum after precipitation of 1; 3, rabbit No. 1, ovalbumin precipitate redissolved in ovalbumin; 4, ovalbumin; 5, free hapten, sodium *p*-amino-benzoate; 6, rabbit No. 1, supernatant as in (2) plus free hapten (5)

showed the presence of all four allotypes; but the precipitate with the conjugate (in this case *p*-COOH-phenyl NCS guinea pig albumin) redissolved in hapten (sodium *p*-amino-benzoate) showed elimination of the *A* allotype using six different anti-*A* sera, and probably of the *D* allotype also—the faint line in Fig. 2 with anti-*D* serum is probably due to another allotype system (see Figs. 1 and 2); it was not evident against two other anti-*D* sera. Fig. 3 shows the reaction with anti-*F* serum and demonstrates also that adequate γ-globulin was present in the redissolved precipitate (6); the reaction with anti-*E* serum was essentially similar.

This particular anti-hapten antiserum (No. 1) was a weak one, but neither this nor the exact nature of the hapten is likely to be involved in the anomalous result, since three of the *DF* animals had antibodies against this same hapten, one equally weak in antibody. Clearly a qualitative test of this kind is inadequate to show a complete elimination of one allotypic γ-globulin from antibody, and more extensive quantitative studies will be needed to confirm and generalize any theoretical conclusions. Nevertheless, in the case of antiserum No. 1, the only one with the possible exception of No. 8 where there was a fair range of allotypes to choose from, at both the *A* and the *D* locus, there seems to be evidence for preferential selection of one kind of γ-globulin synthesizing site, so long as a truly 'mono-specific' (anti-hapten) antibody is examined.

If this is a general phenomenon, it confirms that allotypes determined by allelic genes occur on different molecules: its bearing on clonal selection and other theories of antibody production remains to be determined.

We thank the Medical Research Council for financial support for this work.

INHIBITION OF CELLULAR ADHESION AND PSEUDOPODIA FORMATION BY A DIALYSABLE FACTOR FROM TUMOUR FLUIDS

By Dr. BO HOLMBERG

Cancer Research Division of Radiumhemmet, Karolinska Institute, Stockholm, 60

It has been found that interstitial tumour fluids, in contrast to normal interstitial fluid, contain a dialysable factor deleterious to cultured strain *L* cells. The general observations on this strain as well as on the behaviour of other cell types tested suggest that this factor primarily reacts with the cell surfaces; the induced changes seem irreversible and lead, at least in the case of *L* cells, ultimately to death of the cell. This observation is of interest since it would explain a number of cytolysing effects previously observed in the stromal compartment of tumours[1] and in mixed *in vitro* cultures[2].

The original observations were made with interstitial fluid from Walker rat tumours and solid Ehrlich–Landschütz hyperdiploid (ELD) transplants in *C3H* mice. When strain *L* cells were incubated in such fluids they became cytolysed after 6–12 hr., whereas ELD ascites tumour cell suspensions were unaffected. No hæmolysis of normal mouse blood was noted under these conditions.

The early effects on strain *L* cells by the addition of small amounts of fresh interstitial tumour fluid to the incubation medium involve a nearly complete inhibition of pseudopodia formation and cell adhesion, usually visible shortly after incubation. This could be used as a convenient and rapid test method simply by calculating the frequency of strain *L* cells adhering to the glass by means of pseudopodia after a standardized time of incubation in Carrel flasks[3]. In control flasks containing only the cultivation medium 80–95 per cent of the cells adhere to the glass soon after the incubation (Fig. 1). The deleterious effects on cell growth and cell vitality were estimated in suspension cultures of strain *L* cells by cell counts and Lissamine green permeability tests[4]. A more sensitive test method may in future be worked out using the sedimentation reaction of cells.

Addition of newly collected non-injured strain *L* cells to an incubation medium containing interstitial fluid from solid ELD or mouse mammary carcinomas did not lead to normal cellular adhesion (Fig. 2). The majority of the cells remained rounded and freely floating. This effect could also be obtained by addition of blood plasma from ascites tumour-bearing

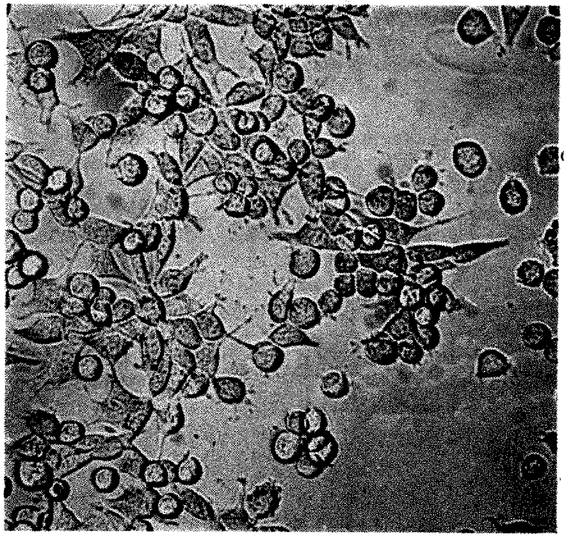

Fig. 1. Strain *L* cells incubated for 3 hr. in Eagle's medium + 20 per cent 0·05 *M* phosphate buffer (× *c*. 660). 80 per cent of cells adhering

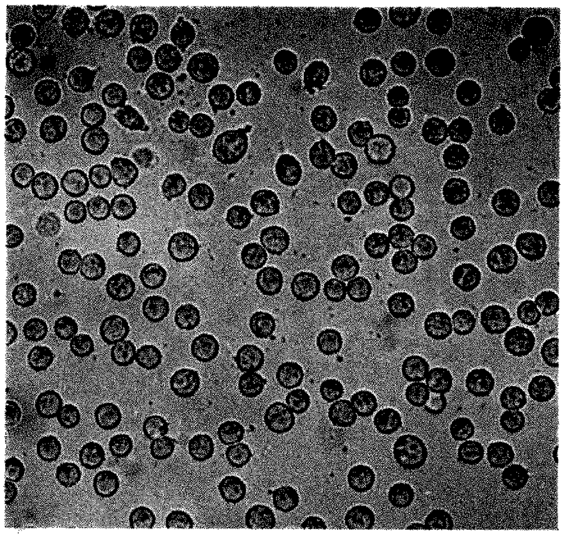

Fig. 2. Strain *L* cells incubated for 3 hr. in Eagle's medium + 20 per cent of the 0·05 *M* phosphate buffer fraction of dialysed ascites fluid (× *c*. 660). 8 per cent of cells adhering

mice, but not with normal mouse plasma. The cell-free ascites tumour fluid obtained at the end of ascites tumour growth was also active and has since been used for isolation of the active component.

Following dialysis overnight of the fresh or slightly autolysed ascites tumour fluid the membrane-active principle was, much to our surprise, found in the dialysate. Serum albumin marked with bromophenol blue was added to the ascites fluid in some cases to ensure that the bags were not defective. The dialysate could be concentrated by evaporation and also freeze-dried without loss of activity. A marked growth inhibition and cytolysing effect was noted when the crude dialysate was added to suspension cultures of strain *L* cells growing in Eagle's medium + 15 per cent horse serum (Table 1).

Table 1. EFFECT OF A CRUDE DIALYSATE* ON STRAIN *L* CELL GROWTH AND VITALITY DURING SUSPENSION CULTURE CONDITIONS IN EAGLE'S MEDIUM + 15 PER CENT HORSE SERUM

Cultivation (hr.)	Controls: Cell conc. 10^6 cells/c.c.	Controls: Cells permeable to LG† (per cent)	Factor added: Cell conc. 10^6 cells/c.c.	Factor added: Cells permeable to LG† (per cent)
0	0·19	3	0·19	3

21	0·27	3	0·20	9
29	0·30	3	0·16	10
48	0·35	4	0·12	21
72	0·37	4	0·05	70

* Total amount of factor present in the culture medium would correspond to a 4 per cent concentration of ascites fluid.
† See ref. 4.

The active factor was then fractionated from the crude concentrate by means of gel filtration on a small 'Sephadex' column, the active material being eluted with distilled water. The active rapidly moving biuret-positive[5] material was further fractionated on a DEAE-cellulose column and eluted with *p*H 7 phosphate buffers at molarities of 0·046–0·100. Repeated fractionations of the biuret-positive material finally gave a sub-fraction eluted by 0·050 *M* phosphate buffer, which seemed to contain the material active against strain *L* cells (Fig. 3).

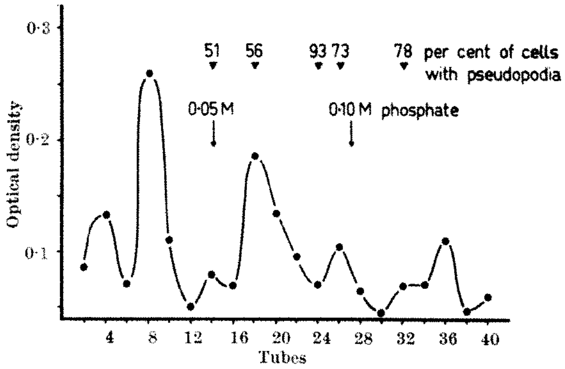

Fig. 3. Chromatographic separation of dialysate obtained from ELD ascites fluid on DEAE-cellulose with phosphate buffer at *p*H 7·0. Optical density refers to the absorption at 750 mμ after addition of the Folin–Ciocalteau's reagent

The ascites fluid activity was apparently associated with a dialysable polypeptide fraction. Its molecular weight was estimated to be 3,000–10,000. Qualitative tests for nucleotides, polysaccharides and lipid material were negative. Cholesterol was absent. Incubation of *L* cells in petroleum-ether extracts of crude dialysates indicated that this lipid material was not active. Following heat treatment of 65° C. for 30 min. the purified fraction still retained an appreciable activity.

The fraction eluted by 0·05 *M* phosphate caused a marked inhibition of pseudopodia formation and of strain *L* cell adhesion both to glass and plastic. This fraction alone, however, did not lead to irreversible cell injury or cell death during the first 2 hr. of incubation. Prolonged treatment of cells growing in suspension cultures is, on the other hand, harmful even at low concentrations.

The isolated fraction further caused withdrawal of pseudopodia in primary glass cultures of ELD ascites tumour cells and Chang liver neoplastic cells established on the glass surface, but without any signs of irreversible cell injury.

2 hr. incubation of strain *L* cells or ELD ascites tumour cells in Krebs–Ringer-phosphate in presence of the active component did not alter the oxygen consumption or the per-cell enzyme activities of lactic dehydrogenase[6], glutathione reductase[7] or cathepsin at *p*H 4·5 (ref. 8).

The sedimentation-rate of normal mouse and human blood cells became slightly retarded by addition of the 0 05 M phosphate fraction, while the sedimentation-rate of blood from ascites tumour-bearing mice or advanced cancer patients was uninfluenced by added factor (presumably due to its presence prior to testing) The sedimentation-rate of L cells, made visible by means of crystal violet staining, was significantly retarded at room temperature by addition of the factor, but the sedimentation-rate of stained ascites tumour cells was uninfluenced

Single intraperitoneal injection into normal mice of the crude dialysate led to a six- to eight-fold rise in the plasma lactic dehydrogenase activity in one week This level of activity was retained for at least 1-3 months The plasma activity of mice injected with factor was not transmittable to untreated mice stored in the same cages The relations if any, to the virus-like agent studied by Riley *et al*[9] and to the polypeptide material purified from the toxohormone[10] remain to be investigated

In some experiments an inhibition of pseudopodia formation could be observed already a few minutes after incubation, suggesting that the active component had reacted with the L cell surface immediately following exposure The subsequent growth inhibition and cell death observed later on cannot be explained at present

Two conditions seem of particular physiological interest One is that the small-size membrane-active factor exists in tumour fluids in a free state allowing diffusion and transportation via the blood stream It may thus have a bearing on the systemic tumour-host relations as yet poorly understood Secondly, the lack of detectable polysaccharide and lipid material seems to imply lack of antigenicity Further investigations regarding the nature and sources of this factor are in progress

This investigation was supported by grants from the Swedish Cancer Society, the Jubilee Fund and the Jane Coffin Childs Memorial Fund

AMMONIA TOXICITY AND *p*H

By DR. KENNETH S. WARREN

National Institutes of Health, National Institute of Allergy and Infectious Diseases,
Laboratory of Parasitic Diseases, Bethesda

THE deleterious effects of ammonia have been a matter of great interest to investigators in many fields of biological and medical research Its passage into cells and hence its toxicity has been studied in *in vitro* preparations from rhododendron petals to red blood cells, in intact plants from onions to peach trees, in parasites, in fish and finally in mammals from mice to men In many circumstances, however, ammonia appears to be a remarkably non-toxic substance Ammonium compounds not only provide the bulk of the world's fertilizer supply, but are useful therapeutic agents for a variety of human ills Furthermore, when the LD_{50} of ammonium chloride is compared, on an m equiv /kgm basis, to that of many other common drugs the ammonium salt appears to be relatively non-toxic When administered or absorbed at a slow rate, vast quantities of ammonia may be tolerated by most living organisms because of their highly efficient detoxifying mechanisms in which urea, glutamine or asparagine is formed

This relatively benign appearance of ammonia may undergo a radical change, however, simply by an alteration in the hydrogen ion concentration of the medium Ammonia at low *p*H is usually toxic only in overwhelming quantities, whereas at high *p*H much smaller amounts may be lethal This variability in the toxicity of ammonia has been studied by many groups of investigators with great success However, the correlation between toxicity and the dynamic equilibrium of ammonia between intra- and extra-cellular fluid governed by the hydrogen ion concentration has only recently been established in mammalian studies

An attempt will be made here to present some of the physico-chemical factors governing ammonia toxicity, and to discuss the independent work done on this subject in many different fields The common bond among these investigators lies in either a basic interest in the mode of passage of weak acids and bases into cells or on observations of ammonia toxicity in relation to such diverse phenomena as the use of nitrogenous fertilizers, the bacterial contamination of cultures of parasitic nematodes, the effect of polluted waters on fish, the use of urea as a nitrogen source for ruminants, the development of meat intoxication in Eck-fistula dogs, and the occurrence of coma in patients with liver disease

In most biological fluids ammonia exists in two forms, the relative proportions of which are determined primarily by the *p*H of the solution Since toxicity depends on the ammonia which enters the organism, and thence the cell, it is of particular importance that cell membranes are relatively impermeable to one form (ionized ammonia), whereas the other (un-ionized ammonia) passes tissue barriers with ease[1]

The proportion of the total ammonia concentration which is ionized at any given *p*H is governed by the dissociation constant of the molecule The *p*K itself may vary with temperature and type of solution In blood plasma the *p*K*a* of ammonia was found to be 9 02 with a range of from 9 1 at 32° C to 8 91 at 41° C. (ref 2) With the appropriate *p*K value and a knowledge of the total ammonia concentration and solution *p*H, the relative proportions of ionized and un-ionized ammonia can be calculated simply by applying the law of mass action (At *p*K*a* 9 0 the respective percentages of un-ionized ammonia at *p*H 6, 7, 8 and 9 are approximately 0.1, 1, 10 and 50.) These calculations are necessary because prevailing methods of ammonia measurement, which are mainly by microdiffusion, provide only the total concentration. Recently, the concentration of un-ionized ammonia in the blood of dogs was determined by measuring the excretion of ammonia gas by the lungs[3]. The experimental findings agreed with those calculated from a knowledge of the total blood ammonia concentration and the blood *p*H.

Since ammonium ions do not cross cellular barriers at an appreciable rate, and un-ionized ammonia does so freely, an equilibrium occurs which is dependent primarily on the *p*H on both sides of the barrier[1,4]. Under normal conditions, a *p*H gradient exists between the intra- and extra-cellular fluids. When this gradient is changed, by an alteration of *p*H on only one side of the membrane or on both sides in opposite directions, a redistribution of ammonia occurs. However, *p*H changes can occur on both sides in the same direction. Then the redistribution of ammonia is either less pronounced or non-existent, depending on the initial *p*H gradient and difference between intra- and extra-cellular buffering capacity. The following equation expresses these relationships:

$$\frac{\text{Concentration intracellular}}{\text{Concentration extracellular}} = \frac{1 + 10^{(pKa - p\text{H}_{\text{intra}})}}{1 + 10^{(pKa - p\text{H}_{\text{extra}})}}$$

Changes in *p*H on both sides of cellular barriers as thus described can be easily induced. Since hydrogen ion penetrates most biological membranes at extremely slow rates, the *p*H on only one side of a membrane can be altered by the addition of fixed acid or base. If carbon dioxide is either added or removed, however, it crosses membranes quickly and easily, and the *p*H on both sides is changed almost simultaneously. These effects have been demonstrated experimentally by carbon dioxide equilibria[5], the use of natural and supravital indicator dyes[6], the distribution of weak acids such as 5,5-dimethyl-2,4-oxazolidine-dione[7], and recently by direct intracellular electrometric measurements[8].

The investigations reported here have been divided into the following sections: *in vitro*, plants, parasites, fish, ruminants, biomedical research and humans.

In vitro. In addition to his classical experiments on the hæmolytic effects of ammonium salts[9], Jacobs studied ammonia passage into cells in many different *in vitro* systems. By using red hybrid rhododendron blossoms, which contain a natural indicator dye[6], he could observe changes in intracellular *p*H with solutions of ammonia. No change in colour was observed with acid ammonium sulphate, but on the addition of a trace of ammonium hydroxide, raising the extracellular *p*H to 6.2, there was a prompt alkaline colour change. Starfish eggs stained with neutral red were the object of another series of investigations[6]. They were placed in three solutions of the same molarity and of the identical hydrogen ion concentration—*p*H 7.2. There was no change in colour in the eggs in the first solution, which was mainly sodium chloride; those in the second, saturated with carbon dioxide, turned bright pink, indicating a fall in intracellular *p*H, while those in the third, which contained ammonia, turned yellow, showing a rise in *p*H.

Plants. "Ammoniak als Alpha und Omega des Stickstoffumsatzes in den Pflanzen" was the title of one of the early papers by Prianischnikov[10]. To-day, this appears to be particularly true in that ammonia is not only essential for the growth and nutrition of plants but may also be responsible for manifestations ranging from inhibition of growth to death. Ammonium hydroxide is the simplest and cheapest source of nitrogen for growing plants, now that the bulk of the world's fertilizer is synthesized from atmospheric nitrogen[11]. Unfortunately, it has been found that this form of ammonia may be highly toxic, and is probably responsible for a host of plant diseases, including exanthema of lemons and lettuce root rot. The latter disease has been practically eliminated by lowering the *p*H of ammonium hydroxide with nitric acid[12].

Since large amounts of free ammonia in solutions at high *p*H may enter plants so rapidly that their protective mechanisms are overwhelmed, it becomes necessary, in order to attain maximal growth with minimal toxicity, to adjust not only the total ammonia supply but also the *p*H of the solution. Davidson and Shive[13], in their investigations of peach trees grown in sand culture, fertilized with ammonium sulphate, found an average rate of nitrogen absorption, linear growth and increase in wet and dry weight over an entire growing season to be more than double at *p*H 6 than at *p*H 4. Earlier experiments performed at *p*H's 4, 6 and 8 revealed increasing ammonia absorption with each increment in *p*H, although maximal growth was achieved only at *p*H 6.

Parasites. Von Brand and Simpson[14] reported that ammonia toxicity may explain the poor survival of parasitic worms in media contaminated with *B. subtilis* or *E. coli*. The authors found an increase in the concentration of ammonia with time in filtrates of bacterial cultures. When the parasites (*Eustrongylides ignotus*) were placed in the various filtrates, their survival-time was reciprocally related to the ammonia concentration. When sodium hydroxide was added to each of the media, the parasites perished much more rapidly. The authors noted that the toxicity was due to free ammonia, and found that acidified solutions were quite harmless.

Fish. Increased concentrations of ammonia found in polluted waters have been observed to be lethal to fish. The *p*H of the water has been found to be a factor of considerable importance in the development of this form of intoxication. One group of investigators[15] carried out their investigations at both *p*H 7 and 8. They found that ten times as much ammonium chloride had to be added to water at *p*H 7 to achieve a killing-rate comparable with that at *p*H 8. Theoretically, these results were fully expected since in aqueous solution at *p*H 7 only 1 per cent of the total ammonia is un-ionized, whereas, at *p*H 8, 10 per cent is in the freely permeable form.

Wuhrmann *et al.*[16] found that fish maintained in water at a high *p*H containing 10.1 mgm. of ammonium sulphate showed toxic manifestations in 70 min., whereas those in a concentration 16.5 times higher, but in which the aquarium was maintained at a lower *p*H, were unaffected for 170 min.

Ruminants. Ammonia intoxication has been reported in ruminants given urea as a supplementary nitrogen source, and in those fed on spring pasturage, rich in non-protein nitrogen. The ammonia was produced by bacteria in the rumen. Recently, the effect of *p*H on the absorption of ammonia from the rumen was studied. Lewis[17] placed ammonium chloride, ammonium acetate or urea in the rumen, causing, respectively, a fall in blood *p*H, no change, and a rise in blood *p*H. The earliest signs of toxicity were seen in the sheep fed urea, in spite of their having the lowest blood ammonia concentrations. Although similar blood ammonia concentrations were found in the animals given ammonium chloride and acetate toxic signs appeared somewhat earlier in the animals fed the acetate salt.

Hogan[18] examined the effect of *p*H on the passage of ammonia from the rumen of sheep. When an ammonia-containing buffer at *p*H 6.5 was placed in the rumen, transport increased with the concentration gradient. At *p*H 4.5, however, the concentration of ammonia in the rumen did not affect its rate of passage across the epithelium. Net loss of ammonia nitrogen from the rumen at *p*H 6.5 was more than three times that at *p*H 4.5. When carbon dioxide was bubbled through solutions in the rumen there was no change in the rate of transport of ammonia.

Biomedical research. In 1894, Pio Marfori[19] published an investigation in which he administered three ammonium salts to dogs and rabbits. He found that ammonium lactate and tartrate were tolerated better than the carbonate salt. He concluded that this was due to the greater dissociation of ammonium carbonate in blood and to the larger quantity found in the free state. Gyorgy and Kleinschmidt[20] in 1927 noted that meat-fed Eck-fistula dogs which were presumably suffering from ammonia intoxication, improved markedly following the oral administration of hydrochloric acid.

More recently Lawrence *et al.*[21] reported changes in the plasma total ammonia-levels of dogs subsequent to an alteration of blood *p*H. Warren[22] working with mice found a differential toxicity of ammonium salts which was related to their effects on blood *p*H. Further experiments in mice revealed increased passage of ammonia into the brain with alkaline salts[23]. Stabenau *et al.*[4] then emphasized the importance of the *p*H gradient on either side of a semipermeable membrane, in this case, the blood stream and the cerebrospinal fluid, brain and muscle. Nephrectomized dogs were infused with ammonia until the blood level reached a steady state. When the blood *p*H was altered by infusions of acid or base the cerebrospinal fluid *p*H remained relatively constant, bringing about a redistribution of ammonia. When carbon dioxide concentration was altered cerebrospinal fluid *p*H changed along with blood *p*H, and there was no significant redistribution of ammonia.

Human beings. Relman *et al.*[24] have recently reported two cases of severe acidosis caused by the ingestion of huge quantities of ammonium chloride. No signs or symptoms of ammonia toxicity were noted. Ammonium salts have been infused intravenously into human beings in the course of studies on the rate of passage of ammonia into the tissues[25]. Very slight, if any, adverse effects were noted. Ammonium chloride was also infused into several patients with alcoholic cirrhosis of the liver with an adverse effect on only one patient[26]. However when patients with severe metabolic alkalosis due to pyloric obstruction were treated with infusions of ammonium chloride definite signs of ammonia intoxication were observed[27,28].

Recent studies[29] in patients in hepatic coma with high blood ammonia concentrations have shown that infusions of hydrochloric acid or sodium bicarbonate can change the blood-cerebrospinal fluid distribution of ammonia. Experiments with carbon dioxide, undertaken on the assumption that the *p*H effect would be similar to that of fixed acid, resulted in a definite deterioration of the clinical state of the patients[30]. In the previous work in which fixed acid was infused, most of the patients were in a terminal state and no significant change in their condition was noted[29]. Large oral doses of lactic acid, however, have been found to be effective in the management of hepatic coma[31].

The phenomenon of the effect of *p*H on the toxicity of ammonia is one that appears to be universal throughout Nature from the onion to man. This problem has been examined by biologists and medical scientists for more than sixty years. One of the most striking aspects of the accumulated literature is its revelation of the almost complete lack of cross-communication among the botanists, ichthyologists, parasitologists, veterinarians, physiologists and physicians.

The following example of the potential value of such communication might be cited. A recently discovered diuretic, chlorothiazide, has precipitated episodes of hepatic coma, usually thought to be due to ammonia intoxication, by inducing potassium deficiency[32]. It is known that potassium depletion in the mammal results in an intracellular acidosis accompanied by an extracellular alkalosis[33], a situation that should maximally enhance passage of ammonia into cells. Support for this thesis might[34] be found in an earlier study of plant physiology in which ammonium-fed, potassium-deficient tomato plants wilted and died rapidly, whereas those given potassium grew luxuriantly. Further work revealed that the leaves of the deficient plants contained five times as much ammonia nitrogen as their normal counterparts.

GROWTH ANALYSIS OF MICE SUBJECTED TO HIGH GRAVITY

By CHARLES C. WUNDER, DUANE WOMBOLT and E. N. OBERG

Departments of Physiology and Mathematics, State University of Iowa

CONTINUAL exposure of various organisms to high gravity as simulated by continual centrifugation can result in reduced growth[1-4]. With some forms, this response can be analysed by simple mathematical procedures[2]. However, owing to the complex nature of mammalian growth patterns, such procedures would not be applicable with mice. The primary purpose of this article is to introduce an approach which, although it does not overlook certain complexities, simplifies their analysis.

The response of the mice is the type expected when developing animals are exposed to a detrimental environmental agent. Three phases of this response are measured by the method described here: (1) a temporary decrement in growth-rate which can be so drastic as to cause negative growth (decrease in mass), (2) a gradual recovery of the growth process, (3) a permanent or long-term decrement which demonstrates itself after several weeks of exposure. Those interested in examples of unrefined data are referred to previous publications[4-6]. Such data are not well suited for direct evaluation of the influence of gravitational intensity and of age on these three phases.

Data analysed in this article are for male white mice of the *NLW* strain. These animals were centrifuged from the age of 3, 4, 5, 7 or 9 weeks for the remainder of their lives at fields of 1.5–10 times the Earth's gravity. Approximately six mice were used for each experimental condition. Techniques and equipment are essentially the same as that described elsewhere[4].

Data were simplified by use of a "physiological time-scale"[7]. One physiological week is arbitrarily defined as the average time required for 50 control mice to increase in size by 2 gm. This means that a straight line would be expected when control masses are plotted as a function of this time-scale. Any systematic deviations from a straight line would be attributed to experimental factors. Growth-rates in gm./physiological week for experimental mice were calculated with the aid of a digital computer from daily or weekly measurements of mass. These rates, as a function of physiological time p since onset of exposure, were fitted to an empirical equation by means of an analogue computer.

The empirical equation to which data were fitted is as follows:

$$\text{growth-rate} = -ae^{-rp} + Ye^{-lp}$$

where Y, a, r and l are positive parameters. Control growth-rate is represented by Y. For this equation all values use units of physiological time rather than actual time. However, the values shown in the figures have been converted to those using real time.

It is anticipated that, in future investigations, the integrated form of this equation would be more satisfactory for computer work. This would give measured mass, itself, rather than rates as a function of p.

The experimental constants a, r and l were evaluated separately for each experimental condition. The symbol a is initial decrement in growth-rate during the first phase of response when the exponential terms would be quite small. The acceleration constant r serves as an index of how fast recovery can occur during the second phase of response. The deceleration constant l serves as an index of the speed for onset of the long-term decay in growth-rate during the final phase.

The coefficients as a function of field intensity are shown in Figs. 1 and 2. Division of a by the mass

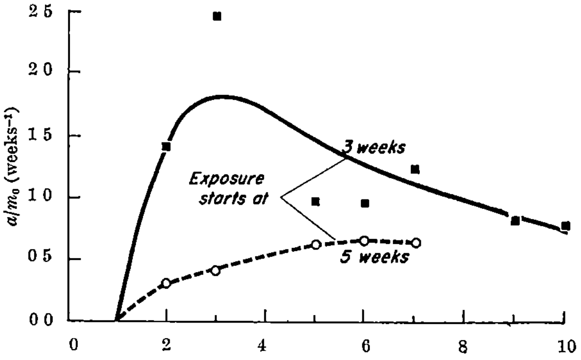

Fig. 1. Temporary decrement in growth constant (a/m_0) versus field intensity. The ratio a/m_0 is used so that the relative magnitude of the decrement can be compared for animals of different sizes. The symbol m_0 refers to body-mass at the onset of exposure

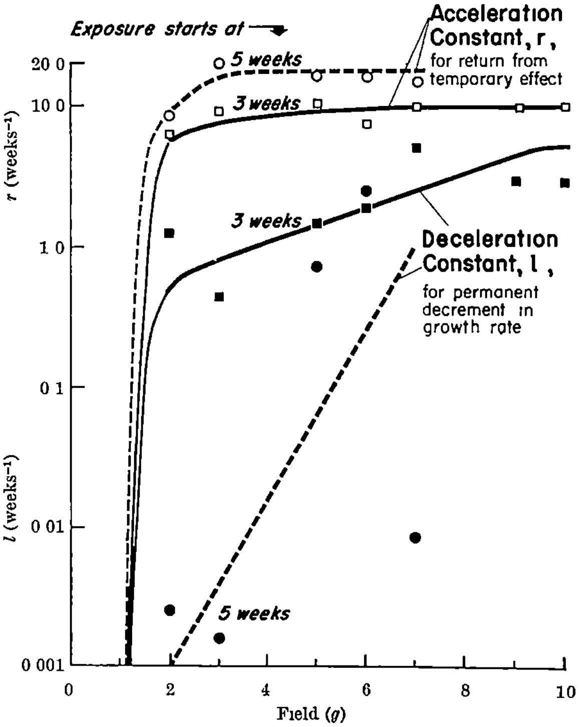

Fig. 2. Influence of centrifugal field intensity on the exponential coefficients

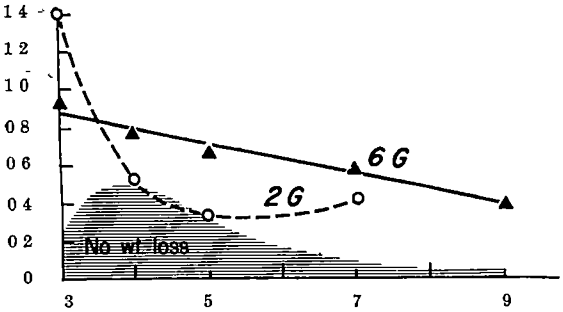

Fig 3 Temporary decrement in growth constant (a/m_0) as influenced by initial age of mouse The height of the shaded areas indicates the magnitude of the control growth constants Y/m_0 When this height just equals that of the experimental points, growth is arrested but no mass loss occurs The fractional decrement in growth constant can be obtained on division of the experimental values by the appropriate vertical extent of the shaded area

m_0 at the onset of exposure gives the initial decrement per unit of body-mass This permits a more meaningful comparison for mice of varying size The ratio a/m_0 can be thought of as the temporary decrement in the growth-constant (growth-rate/unit mass) Although results for newly weaned mice (three weeks old) are somewhat scattered, progressively greater decrement as the field increases is evident for older mice (Fig 1) Fields of six times the Earth's gravity have a more marked effect on the older mice This appears to be contrary to results obtained with fly larvæ[8] However, preliminary computations which involve corrections for changes in control rates Y with age have yielded results which are in better agreement with the data for fly larvæ[9]

On the basis of values for r at fields of 3–10g, recovery-rates are largely dependent on the extent of the decrement (a) rather than being directly dependent on the field intensity (Fig 2)

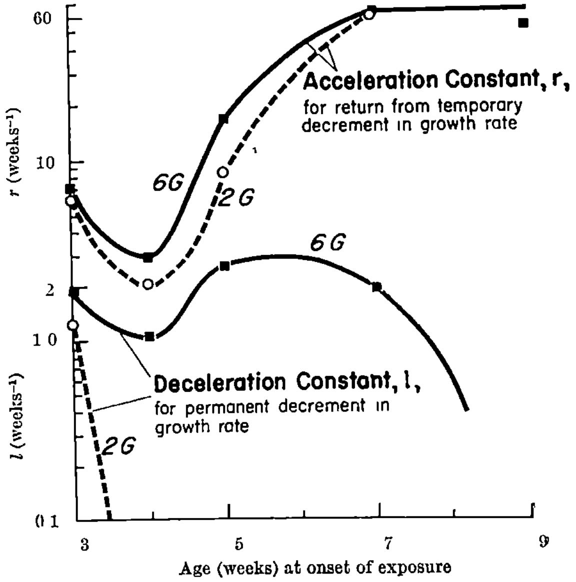

Fig 4 Little or no long-term effect as indicated by values for l could be detected at $2g$ for mice older than 3 weeks

MECHANISM OF SENSITIZATION TO ULTRA-VIOLET LIGHT OF *T1* BACTERIOPHAGE BY THE INCORPORATION OF 5-BROMODEOXYURIDINE OR BY PRE-IRRADIATION OF THE HOST CELL

By PAUL HOWARD-FLANDERS, RICHARD P BOYCE and LEE THERIOT

Department of Radiology, Yale University School of Medicine, New Haven, Conn

THE replacement of thymidine by 5-bromodeoxyuridine (BUDR) in deoxyribonucleic acid (DNA) increases the sensitivity to ultra-violet light of mammalian cells, bacteria, viruses and transforming principle[1–9] Several explanations may be considered. (1) The greater sensitivity to the ultra-violet light wave-length 2537 Å is not due to any increase in the energy adsorbed, as the extinction coefficient of thymine exceeds that of bromouracil at this wave-length (2) The greater sensitivity may in part be due to a greater photochemical effect on the bromouracil than on the thymine in DNA Smith[10] found that BUDR-containing DNA is more sensitive than native DNA to ultra-violet light The rate of loss of bromouracil is 1 9 times greater than that of thymine from the DNA of *E coli B/r* when irradiated *in vivo* (3) Sensitization may also be due to the inhibition of certain enzymes as was shown in experiments with $\overline{T2u}$ and $\overline{T2u^+}$ bacteriophage by Stahl *et al*[8] The action of either the *u*-gene or photoreactivation will eliminate about half the ultra-violet injuries in normal, but not in BUDR-substituted DNA In addition, the pyrimidine analogue can increase the sensitivity of $\overline{T2u^+}$ by as much as two-fold Sauerbier[9] found that BUDR-containing *T1* phage is not photoreactivated, that it is much more sensitive to ultra-violet light, and that host cell reactivation is reduced. The term 'host cell reactivation' refers to the greater survival of ultra-violet-irradiated *T*1 when adsorbed to normal rather than to pre-irradiated *E. coli B* (refs. 11 and 12).

Further insight into the processes of reactivation has been gained as the result of the discovery by Hill[13] of a radiation-sensitive mutant B_s among the survivors of ultra-violet-irradiated *E. coli B*. Ellison, Feiner and Hill[14] found that *T*1 bacteriophage appeared to be more sensitive to ultra-violet light when plated on the sensitive strain B_s than when plated on *B*. The different levels of survival can be explained by the supposition that a factor capable of reactivating certain ultra-violet injuries in DNA is present in *E. coli B*, but is missing in B_s. It is of particular interest that ultra-violet irradiated *T*1 can be photoreactivated after infecting either strain, indicating that the dark reactivation factor in *B* acts on injuries that are not photoreactivable. Moreover, it does not act on ultra-violet irradiated *T*2 or *T*4, as the survival of these phages is the same when plated on either *B* or B_s. It is not clear from these results whether they reflect the action of one or of several reactivation factors.

In this article we report some additional results on the reactivation of ultra-violet injuries in *T*1 bacteriophage. The experimental approach is to examine the sensitization of *T*1 bacteriophage which results from the incorporation of BUDR, and how this is affected by plating on *E. coli B* and on the radio-sensitive strain B_s. Tests are also made on the extent to which the host cell reactivation phenomenon of Garen and Zinder[11] that is found in *E. coli B* also occurs in B_s.

The methods used for preparing the BUDR-substituted phage follow those described by Stahl *et al.*[8] *E. coli B* was grown to a concentration of 10^8 per ml. in medium II containing 20 μgm. per ml. of aminopterin in place of the 10 μgm. recommended. *T*1 bacteriophage were added to a concentration of 3×10^6 particles per ml. and the culture was vigorously aerated. A concentration of about 10^8 phage per ml. was obtained, which was then increased to 1.5×10^9 per ml. by centrifugation. The phage were further purified by centrifugation in a cæsium chloride density gradient so that a dense fraction could be selected. 1 ml. of the concentrated phage suspension was added to 3 ml. of cæsium chloride at 0.8 gm./ml. dissolved in nutrient broth. About 10^7 *T*1 particles grown in normal media and carrying the genetic markers *GeH* were also added to the suspension. The phage were centrifuged in a Spinco swinging bucket rotor *SW* 39 at 25,000 r.p.m. for 26 hr. at about 5° C. The tubes were then pierced at the bottom and the emerging drops were collected in groups of six. This yielded about 35 fractions, of which a dense fraction was selected for use in the experiments with ultra-violet irradiation.

The phage were suspended in buffer and 2-ml. aliquots were placed in a watch-glass with a magnetic stirrer for the irradiation. The phage were irradiated with a partially shielded 15-W germicidal lamp at a distance of 20 cm. The ultra-violet dose-rate measured with a General Electric germicidal ultra-violet intensity meter was 12 ergs/mm.²/sec.

The *T*1 phage stock containing the genetic markers *GeH* and *E. coli B*/1 were obtained from Dr. C. Bresch and the radiation-sensitive mutant *E. coli* B_s was obtained from Dr. R. Hill. The phage were plated on either *E. coli B* or B_s. *GeH* mutants were recognized by plating on *E. coli B* mixed with 0.5 per cent *B*/1.

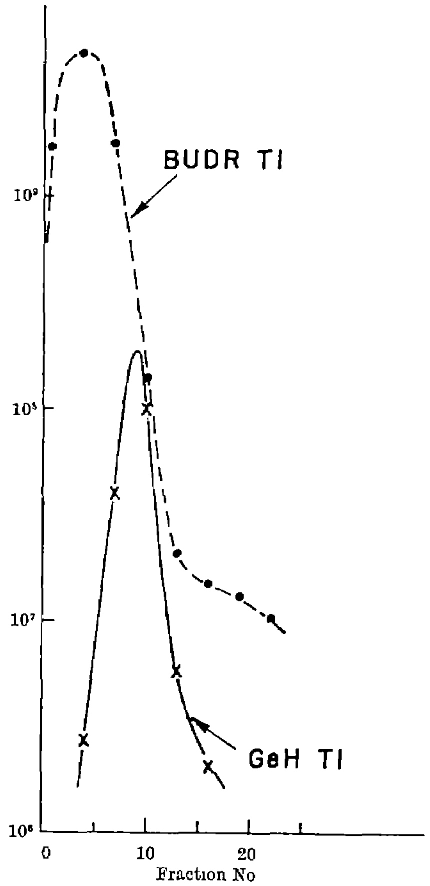

Fig. 1. The number of *T*1 bacteriophage per ml. is plotted against the fraction number from the cæsium chloride density gradient, the first fractions of the greatest density being on the left. Each fraction contains 6 drops from the gradient tube. Fraction number 2 was used in the experiments. The *T*1 phage with the genetic markers *GeH* was added as a density marker and contained no BUDR

The distribution in the numbers of wild-type and *GeH* bacteriophage among the successive fractions from the density gradient centrifugation are shown in Fig. 1. It is seen that at 0.60 gm./ml. cæsium chloride, the density was such that the BUDR labelled *T*1 band was near the bottom of the tube and came out in the early fractions. Samples of normal and the BUDR-containing *T*1 from the second fraction of the density gradient were suspended in adsorption medium at a concentration appropriate for the irradiation experiments. Samples were taken at intervals during the irradiation, diluted and plated on *E. coli B* and B_s. The relations between the number of infective centres surviving and the ultra-violet dose are seen in Fig. 2. It is seen that while BUDR causes a marked increase in the sensitivity of *T*1 when plated on *E. coli B*, it has relatively little effect when plated on B_s.

When ultra-violet-irradiated *T*1 is plated on *E. coli B*, and the logarithm of the number of infective centres surviving is plotted against the ultra-violet dose, as in Fig. 3, a two-component curve is obtained. Fig. 3 also shows the effect of irradiating the bacteria to which the phage were pre-adsorbed before plating. A dose of 240 ergs/mm.² to the host cell increases the steepness and length of the initial part of the curve. At the highest dose tested, 1,440 ergs/mm.², the sur-

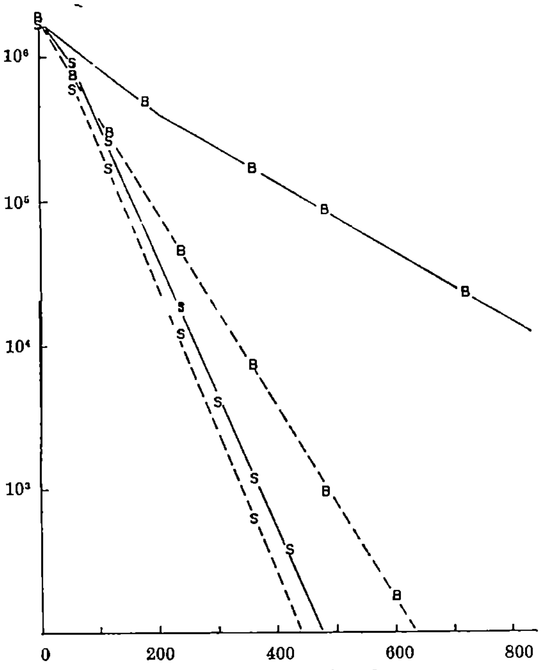

Fig 2 The number of surviving infective centres of *T*1 bacteriophage per ml is plotted as function of the ultra-violet dose delivered to normal and BUDR-containing *T*1 phage when plated on *E coli B* and B_s The dense fraction number 2 in Fig 1 was used in this experiment —, *T*1, – – –, BUDR *T*1, B, *E coli B*, S, *E coli* B_s

vival curve has become as steep as that obtained by plating on *E coli* B_s, and the second component of the curve has been eliminated In similar experiments in which the ultra-violet irradiated *T*1 is pre-adsorbed to *E coli* B_s before plating, a single straight line relationship is obtained and pre-irradiation of the host has very little effect

The results show that the sensitivity of *T*1 bacteriophage to ultra-violet can be increased to about the same extent in any one of three ways (1) by incorporating BUDR in the phage DNA in place of thymidine, (2) by using *E coli* B_s instead of *B* as host, (3) by pre-adsorbing the phage to ultra-violet-irradiated *E coli B* The sensitization produced in three ways is not additive when combined, which suggests that they operate through a common mechanism

The reactivation of ultra-violet injuries without light or *u*-gene action has been demonstrated in other experiments When investigating the loss of ultra-violet-induced mutations in *E coli B* and other bacteria, Witkin[15] and Doudney and Haas[16] found that many factors which increase the time-interval between irradiation and the next cell division also have the effect of decreasing the number of mutants obtained This suggests that the DNA is reactivated if sufficient time is available before the next DNA replication[17] Similarly, there is a reduction in the lethal effects of radiation on bacteria if sub-optimal growth conditions are used[18,19]

If the dark reactivation factor is an enzyme or enzyme system, then like the photoreactivation enzyme[20] it may have an affinity for ultra-violet photo-products in DNA This suggests that the change in the apparent sensitivity to ultra-violet of *T*1 that results from pre-irradiating the host may be due to the enzyme forming a complex with the ultra-violet irradiated DNA of the host cell This would leave none available to act on the ultra-violet-irradiated phage DNA that is afterwards injected It is seen in Fig 3 that an ultra-violet dose to the bacterium of 240 ergs/mm ² is sufficient to inhibit reactivation in the majority of cells, presumably by tying up the reactivation enzyme in this way If only the phage were irradiated, it would take a much larger dose to stop reactivation as there is relatively little DNA in the phage When phage-infected cells are irradiated, the phage DNA is in an unfavourable position to compete for the enzyme, of which much more than 90 per cent might be expected to react with ultra-violet products in the relatively abundant bacterial DNA (and possibly RNA) As a result, there should be little enzyme action on the phage DNA in complexes and therefore, little difference between the sensitivities of the 4 kinds of complexes formed when either normal or BUDR-containing *T*1 phage infect either *E coli B* or B_s This question will be the subject of a further publication

These experiments give little indication of the time taken by the enzyme to reactivate ultra-violet products in DNA Witkin[17] found that the decline in mutation frequency after irradiation occurred in a period of about 10 min The time available for reactivation in *T*1 infected cells is presumably shorter, so that relatively more enzyme may be required if it is to be effective The reactivation enzyme hypothesis affords a coherent explanation of a larger body of data than the proposal by Garen and Zinder[11] and Stent[21] of a mechanism that involves genetic homology and mating between phage and host The presence in the cell of a dark reactivation enzyme that does not act on BUDR-containing DNA must play a part in the sensitization of the bacteria by this thymidine analogue as reported by Greer[3] and Kaplan *et al* [5]

It is concluded that one of the main reasons why *T*1 phage containing BUDR is more sensitive to ultra-violet light is that dark reactivation, presumably

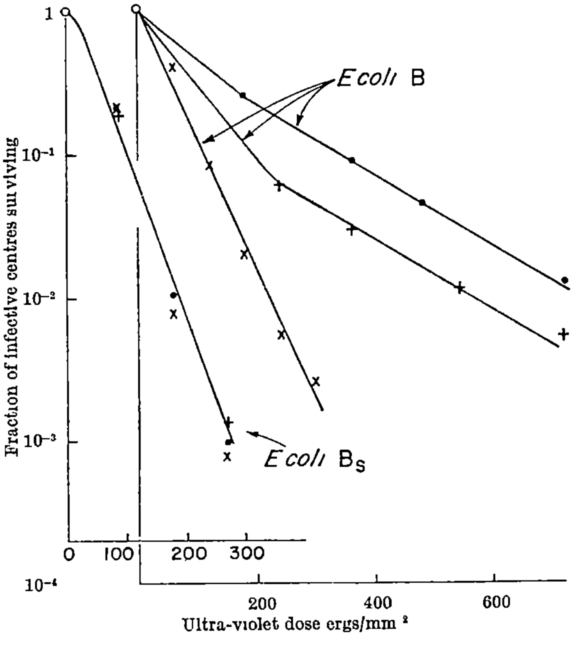

Fig 3 The fraction of infective centres of *T*1 bacteriophage surviving ultra-violet irradiation when pre-adsorbed to normal and irradiated bacteria of strains *E coli B* and B_s The doses given to the bacteria are 0 (●), 240 (+), and 1,440 (×) ergs per mm ²

the work of an enzyme or enzyme system, does not act effectively on BUDR-containing DNA The radiation-sensitive mutant *E coli* B_s (ref 13) lacks the dark-reactivation system

We thank Dr Ruth Hill for the radiation-sensitive mutant *E coli* B_s, and Dr Carsten Bresch for the *GeH T*1 and the *E coli B*/1 This work was supported by grants from the Jane Coffin Childs Memorial Fund and the U S Public Health Service

FOLLICLE PRODUCTIVITY AND GROWTH OF WOOL

By D. A ROSS

New Zealand Wool Industries Research Institute (Inc), Dunedin, New Zealand

SINCE Fraser[1] proposed that wool follicles compete for fibre substrate, a considerable literature on this topic has developed which has recently been reviewed by Fraser and Short[2] Fibres from primary and secondary follicles, or large compared with small fibres, are considered to react differently to changes in nutrition

Over a period of 18 months, wool samples were clipped at monthly intervals from the mid-side position of ten free-grazing full-mouth Romney ewes[3]. Data from only one ewe, which illustrate the relationship between follicle productivity at different levels in the fibre array and the level of wool production in some of these ewes, will be presented in this article

The weight of clean oven-dry wool produced per unit area of skin per day for each month was measured on this ewe and expressed as a percentage of the maximum wool production The minimum level of wool production was 14 per cent of the maximum From each of the 18 monthly samples, 500 fibres were measured for fibre diameter and 150–200 for fibre length The fibre diameter and length arrays were each subdivided into seven groups to enable a study to be made of the effect of changes in the level of wool production at different levels in the array About 15 per cent of the fibres will be of primary follicle origin, and as these will largely be the coarsest and longest fibres they will be principally found in group 1, which consisted of the coarsest or longest 15 per cent of fibres, while group 7 contained the finest or shortest 15 per cent of the fibres Groups 2, 3, 4, 5 and 6 consisted of 15 per cent of the fibres in descending order of diameter or length, except that group 4 contained only the 10 per cent of fibres about the mean Making the reasonable assumption that a fibre occupies the same relative position in an array irrespective of the level of wool production, and that there is a perfect correlation between the diameter and the length of fibres, then three comparisons of follicle productivity in relation to the level of wool production can be made at each of the seven levels in the fibre array These are fibre diameter d, or cross-sectional area d^2, fibre length l, and fibre volume d^2l

Fig 1 shows the regression coefficients, for each group of fibres for these three measures of follicle productivity, for a change of 1 per cent in the level of wool production The values of the regression coefficients for d^2, l and d^2l are plotted against the mean cross-sectional area (d^2) of each fibre group Shown also in Fig 1 are the regression coefficients expressed as percentages of the corresponding cross-sectional areas

The absolute increase in fibre cross-sectional area associated with an increase in the level of wool production increases with increasing fibre cross-section, but expressed as a percentage of d^2 it decreases On the other hand, there was little variation in the fibre length response at the various levels in the array, only a very slight increase in length with increasing fibre diameter (or fibre length) being indicated Again

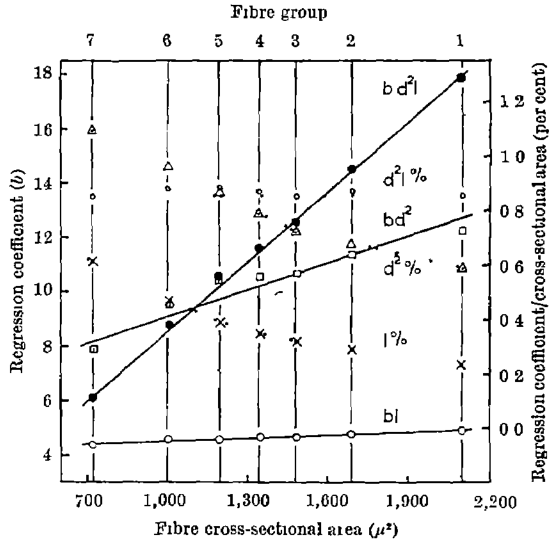

Fig 1 Regression coefficients (b) of d^2 (μ^2), l (μ) and d^2l ($\mu^3 \times 10^{-3}$) for a change in wool production of 1 per cent for each group of fibres, plotted against the mean cross-sectional area (d^2) Also shown are these regression coefficients as percentages of the corresponding d^2

the regression coefficients for the changes in fibre length decrease as a percentage of d^2 (or of l). The volume of fibre produced (with increasing wool production) increases linearly with increasing fibre cross-sectional area within the array, such that the increase *in volume* is a *constant* percentage of fibre cross-sectional area. Per unit area of cross-section, therefore, all fibres, irrespective of size or biological origin, showed the same response in volume to a change in the level of wool production. The wool follicles in this mature Romney ewe therefore have the same 'efficiencies' and do not compete among themselves for fibre substrate.

The following measures of follicle productivity, which have been considered by other workers to indicate follicle competition, arise as a direct result of the relationships which have been found between the level of wool production and d^2, l and d^2l. (1) The ratios of group 1d^2/group 7d^2, group 1l/group 7l or group 1d^2l/group 7d^2l will vary inversely with the level of wool production. Similarly, the ratio of the diameter or length of fibres from primary, compared with secondary, follicles will also vary inversely with wool production. (2) When the follicle productivity of a fibre or group of fibres is considered relative to the mean follicle productivity in the array (for either d^2, l or d^2l), then for fibres above the mean value the follicle productivity will be highest when wool production is lowest, while for fibres below the mean it will increase as the level of wool production rises. (3) The coefficient of variation of fibre diameter will be lowest when wool production is highest.

The interpretation of investigations of the relative follicle productivity of small versus large fibres, based on measurements of either d or l alone, can therefore be misleading. While differences in fibre productivity between follicles have been considered in terms of fibre cross-sectional area, some function of the follicle itself, such as papilla volume or surface area, may be the most appropriate basis for such comparisons.

The results do not indicate that the fibres of group 1, which will be largely of primary follicle origin, respond any differently in this ewe than the other groups which consist of fibres from secondary follicles. As body-weight and consequently skin surface area were approximately constant during this trial, the distance between wool fibres would be at a maximum when wool production was at a minimum, indicating that the spatial relationships of the follicle population of this mature ewe did not affect the relative follicle productivity.

Levels of production in pasture-fed ewes are low compared with the potential maximum level of production. At low levels, the finest fibres cease growing at a diameter of about 12μ in Romneys, while at high levels of wool production the larger fibres may become heavily medullated. As follicle productivity is essentially measured by the mass of fibre produced, in these large medullated fibres, total fibre volume may increase without any accompanying increase in fibre mass or follicle productivity. Five of the ten ewes in this trial contained a high proportion of medullated fibres in the summer months when wool production was high. In these ewes, the change in the volume of fibre produced per unit area of cross-section increased with increasing diameter of the fibres, when wool production increased.

Comprehensive investigations of fibre diameter, length, volume, mass, follicle type and fibre number are necessary before the factors controlling the production of wool, both in the developing and in the mature fleece, are clearly understood.

SEPARATION OF THE OXYGEN EVOLVING SYSTEM OF PHOTOSYNTHESIS FROM THE PHOTOCHEMISTRY IN A MUTANT OF *SCENEDESMUS*

By Prof. NORMAN I. BISHOP
Florida State University, Tallahassee

THE mechanism of the biosynthesis of chlorophyll[1] and of carotenoids[2] has been elucidated successfully with the aid of mutations artificially induced in certain algae, but little use has been made of this technique to solve quite specific questions concerning the mechanism of photosynthesis. The reason may be that it is relatively easy to produce random mutations of photosynthetic organisms and to concentrate on those which show obvious changes in colour, but considerably more difficult to obtain a mutation the desired characteristics of which have been narrowly defined in advance.

In many strains of algae distributed among several species[3] it is possible to substitute a photoreduction with hydrogen for the normal type of photosynthesis, that is, under these 'adapted' conditions no oxygen is evolved in the light. With certain inhibitors it is possible to make the hydrogen-adapted condition semi-permanent[4]. The question arose whether this effect could be brought about in a more natural way.

The isolation and characteristics of a mutant of the green alga *Scenedesmus obliquus*, strain D_3, which is incapable of evolving oxygen in the light but which behaves quite normally otherwise, are discussed here. The mechanisms for respiration, growth and for a photochemical fixation of carbon dioxide have remained unaltered.

Method of mutant production and isolation. Mutations were induced by irradiating samples of a thin algal suspension with a Philips 25–250 X-ray machine for a period of time sufficient to deliver 60 kr. Afterwards aliquots of the algal suspension were spread uniformly on Petri dishes containing a basal nitrate medium[5] plus 1 per cent glucose–0·5 per cent yeast extract. After 12–14 days the surviving colonies of algae were exposed to light and carbon dioxide labelled with carbon-14 by a method previously described by Levine[6]. With this method colonies of cells were occasionally detected which had not incorporated any $^{14}CO_2$. Such colonies were trans-

Table 1 PIGMENT CONTENT OF WILD-TYPE *Scenedesmus* AND MUTANT 11

Algal strain	(*a*) mgm Chl $a+b$ 50 μl cells	(*b*) mgm β-carotene 50 μl cells	(*c*) Total carotenoids 50 μl cells	a/c	a/b	c/b
Wild-type—Heterotrophic	0.405	0.0115	0.076	5.32	35.2	6.60
Photoheterotrophic	0.630	0.0185	0.97	6.49	34.0	5.24
Mutant 11—Heterotrophic	0.370	0.0098	0.064	5.78	37.8	6.53
Photoheterotrophic	0.240	0.0038	0.032	7.50	63.2	8.42

ferred into separate culture tubes, and after sufficient growth had occurred larger-scale culture flasks were inoculated for either photoautotrophic or heterotrophic growth studies. Those cultures which did not grow photoautotrophically, or only poorly, but developed heterotrophically were further scrutinized.

In this way I have obtained a number of mutants which are unable to photosynthesize aerobically. But among these only one, mutant 11, has the specific characteristics which I sought. *Scenedesmus* D_3, mutant 11, shows no aerobic photosynthesis, no quinone-Hill reaction, but a normal capacity for photoreduction under hydrogen. It has a normal growth-rate heterotrophically in dark or light in contrast to other 'green' mutants which have become light sensitive and survive only in the dark[7]. Furthermore, its respiratory rate and also its ability to decompose hydrogen peroxide are identical to that of the normal 'wild' type *Scenedesmus* D_3.

Pigments of mutant 11. Analyses of the chlorophyll *a* and *b*, total carotenoid, and β-carotene content of dark grown cultures revealed a slight decrease in the amount of total carotenoid synthesized by the mutant. This slight decrease is enlarged several-fold when cultures are grown photoheterotrophically (Table 1). The fact that the mutant grows at all in the light heterotrophically speaks against this alteration in pigment content as being the causative factor in this particular genetic block of photosynthesis. The marked change in content of carotenoid during growth in the light must be due to this particular mutant's inability to dispose of the 'precursors' to molecular oxygen which would accumulate in the light. In the normal alga these substances are dismutated to oxygen but in the mutant accumulate and lead to deleterious side-effects.

No change could be seen in the fine structure of the chloroplast of mutant 11 when cells were examined with the electron microscope.

Capacity of mutant 11 *for photosynthesis, photoreduction and the Hill reaction*. Aliquots of a culture of mutant 11 were used for measuring photosynthesis, photoreduction, and the Hill reaction. A culture of normal cells grown under identical conditions served as control. The capacity for photosynthesis is reduced practically to zero. There is not even a compensation of respiration in the light (Fig. 1). Correspondingly, this mutant does not incorporate carbon dioxide to any extent under aerobic conditions. Chromatographic analysis of $^{14}CO_2$ fixation products clearly shows that light does not alter the pattern or the amount of such substances that become labelled during a control dark experiment. No evidence for the appearance of phosphorylated intermediates common to the photosynthetic cycle were detectable. Furthermore, radioactive tracer carbon is predominantly incorporated into compounds where labelling might occur through exchange and not necessarily by synthesis, that is, aspartic acid, glutamic acid, alanine and malic acid.

Mutant 11 is also incapable of reducing *p*-benzoquinone in the Hill reaction. For example, the $Q_{O_2}^{Chl}$ of a normal culture of *Scenedesmus* was 1,444 µl O_2/hr -mgm chlorophyll, while the highest observed value for the mutant was 22 (highest of five separate determinations). This represents a loss of more than 98 per cent of the capacity for this reaction. Furthermore, we do not know that the slight amount of gas produced was oxygen. The same dubious small gas production was also observed in photosynthesis tests (Fig. 1). The nearly complete loss of Hill reaction activity points to a block in the oxygen-evolving mechanism of photosynthesis. Further evidence for this is the excellent capacity of this mutant to perform photoreduction.

After several washings and a 24-hr period of starvation, aliquots of the normal dark-grown *Scenedesmus* and of mutant 11 were adapted in an atmosphere of hydrogen and 4 per cent carbon dioxide for a period of 16 hr. Then the adapted cultures were illuminated for periods of 15 min at varying light intensities and the amount of gas uptake recorded. Typical results for such an experiment are shown in Fig. 2. The mutant has a light-saturated rate of photoreduction of carbon dioxide which approximately equals that of the control. It is remarkable, however, that the rate of photoreduction at low light intensity is appreciably higher in the mutant than in the 'wild type'. Fig. 2 shows also the effect of 3(3,4-dichlorophenyl)-1-1-dimethyl urea (DCMU). We know that this poison strongly inhibits reactions of the photosynthetic system which depend on the evolution of free oxygen, but not those involved in carbon dioxide fixation[8,9]. In Fig. 2 it is clear that mutant 11 without DCMU behaves exactly like the control with DCMU.

The pattern of $^{14}CO_2$ fixation during photoreduction of the mutant and the 'wild' type *Scenedesmus* when examined chromatographically were found to be identical. During photoreduction the well-known phosphorylated intermediates of photosynthesis were

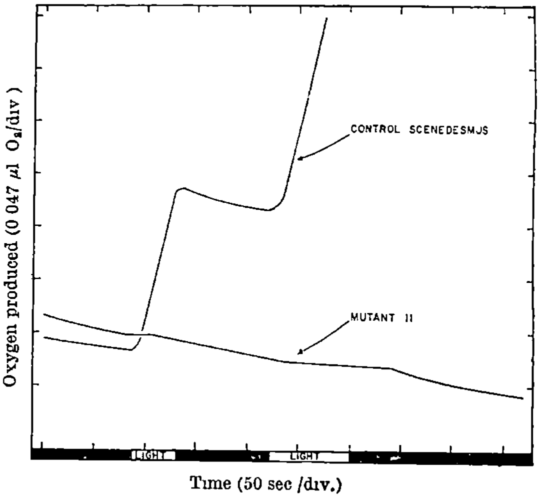

Fig. 1. Polarographic traces of oxygen consumption and production by dark-grown normal *Scenedesmus* and mutant 11. Gas phase = 4 per cent CO_2—96 per cent N_2, temperature = 20° C., cell volume = 15 µl., pH = 6.5, phosphate buffer = 0.05 M, final volume = 2 ml., light intensity = 4 klx.

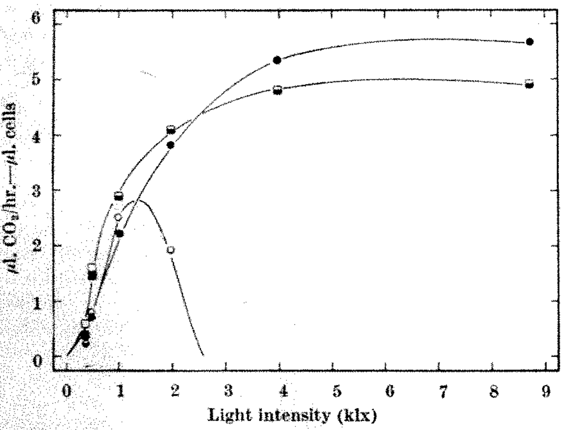

Fig. 2. Rates of photoreduction of dark-grown normal *Scenedesmus* and mutant 11 at various light intensities with and without DCMU (2×10^{-6} *M*). Temperature = 25° C.; phosphate buffer (*p*H = 6·5) = 0·05 *M*; cell volume = 30 μl./vessel. ○–○ = control; ●–● = control + DCMU; □–□ = mutant 11; ■–■ = mutant 11 + DCMU

clearly present, in strong contrast to the $^{14}CO_2$ assimilation pattern observed aerobically. The implications of the lack of photophosphorylation under one physiological condition and its presence in another are of some particular importance, in line of the proposed mechanism of cyclic and non-cyclic photophosphorylation[10]. The point in question is rather obvious: is photophosphorylation in intact photosynthesizing tissue dependent on the integrity of the oxygen-evolving mechanism? This point is at present being investigated with various mutants, including 11.

Analysis of the hydrogenase activity of the mutant in the dark, either with oxygen or sodium nitrite as oxidant, showed that the enzyme was some two- to three-fold more active than that of the 'wild' type. This offers an obvious explanation for the increased rate of photoreduction observed in the mutant. In spite of this higher hydrogenase activity mutant 11 is incapable of any photoproduction of hydrogen as is found normally with algal strains capable of adapting to hydrogen and in some purple bacteria. The implication of this finding is not clear and requires further experimentation.

Certain theories on the evolution of photosynthesis favour the idea that the last major step in the evolution of higher-plant photosynthesis was the addition of a mechanism whereby the oxidant (photoxidant) produced in the photolysis of water could be dismutated directly to molecular oxygen rather than through the energetically inefficient method of reduction via exogenous hydrogen donors. This evolutionary step not only removed the strict dependence of the organism on an organic environment but also opened the way for future Darwinian evolution by providing a means for increasing the oxygen content of the Earth's atmosphere. The addition of this mechanism to the photosynthetic process resulted in a general loss of the enzymes previously involved in the reduction of the photoxidant. The exceptions to this are the few strains of algae which still possess the potential for photoreduction, that is, an adaptable hydrogenase[11].

In mutant 11 we have in a sense reversed the last evolutionary step and again placed the organism into a physiological state where it is dependent on an external hydrogen donor in order to reduce carbon dioxide successfully.

It has been hypothesized that the adaptation process may involve certain subtle changes in an enzyme which in one circumstance functions in oxygen evolution but in the modified form, that is, after prolonged incubation in an anaerobic atmosphere, is temporarily non-functional in reactions leading to oxygen evolution[12]. From this point of view the isolation of a mutant such as No. 11 takes on additional interest. In this mutant the enzyme(s) now function in the more primitive fashion, that is, as hydrogen mediators in the reduction of the photoxidant and not in oxygen evolution. For this reason alone it is of interest to find that in mutant 11 the activity of the hydrogenase is increased several-fold.

In my present experiments I am attempting to determine more specifically the nature of the block to the oxygen-evolving system. So far there are several constituents of chloroplasts which have been implicated in the mechanism of oxygen evolution, that is, cytochromes (b_6 and f), manganese, plastoquinone, and perhaps β-carotene. I am at present investigating whether or not modifications have occurred either in content or requirement for any of these factors.

This investigation was supported by grants from the U.S. Atomic Energy Commission (*AT*–(40–1)–2687), National Science Foundation (*NSF–G*12852), and the Fels Fund.

RECEPTORS IN THE SUCKERS OF *OCTOPUS*

By Dr. P. GRAZIADEI

Department of Anatomy, University College, London

An octopus can collect with its arms various sorts of information. It is able to discriminate by touch between objects with different surfaces. Moreover, when an octopus walks, the tips of the arms are often used to explore the environment. When two octopuses meet they may examine each other with the tips of their arms. Presumably, chemoreceptors as well as tactile receptors are present. In octopuses experimentally blinded the recognition of prey and the movements necessary to capture it and carry it to the mouth are based and co-ordinated by impulses collected by the suckers. Many experi-

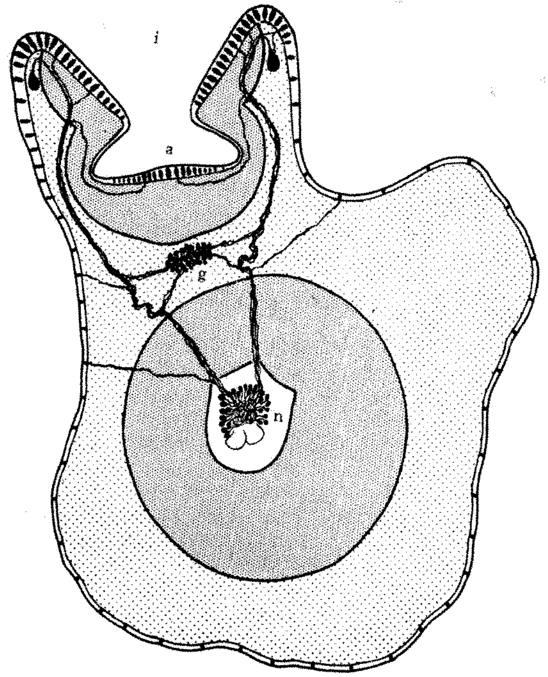

Fig. 1. Transverse section of the arm of *Octopus*. *a*, Acetabulum; *g*, ganglion of the sucker; *i*, infundibulum; *n*, nerve cord of the arm

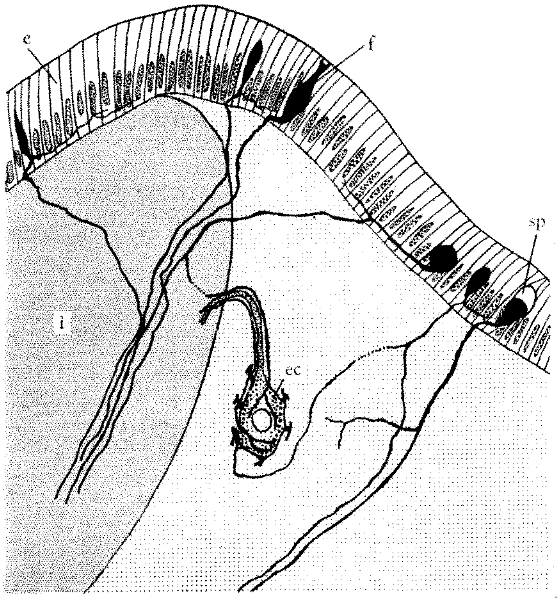

Fig. 2. Detail of the infundibulum of the sucker in *Octopus*. *e*, Epithelium of the infundibular cup and of the rim of the sucker, with numerous primary sense cells; *ec*, encapsulated nerve cell with synapsing fibres; *f*, fusiform-shaped cell reaching the free surface of epithelium where it apparently opens; *i*, infundibulum; *sp*, spheric intraepithelial cell carrying a second sphere of clear cytoplasm

ments have shown that an octopus can discriminate with its arms between objects differing only in small details, such as a smooth surface from one with various degrees of irregularity[1]. All these facts make it especially worth while to examine the receptor apparatus of the arms, and in particular the suckers, in an attempt to find a morphological basis for these findings.

The suckers of several arms of *Octopus vulgaris* (Lamarck) have been used. In each octopus specimens were taken of the suckers at the base and the extreme tip of the arms. The diameter of the suckers, measured at their infundibular openings, varied from 12 to 1 mm. The arms were fixed in 10 per cent neutral formol–sea water and stained modification of Cajal[2] which is particularly suitable for these invertebrates. Other pieces were impregnated by Bielschowsky–Gros.

It is known from previous investigations that the sucker of an octopus has the form of the sections of two cups one on top of the other, having different radii of curvature. The lower one is the acetabulum, the upper one the infundibulum (Fig. 1). A description of the anatomy of the suckers and of the epithelial surfaces has been given in Guérin[3] and by Rossi and Graziadei[4].

In the prismatic epithelium which covers the inside of the infundibulum there are numerous primary sensory cells (Fig. 1). These cells have various forms; in some of them the cell body is round and darkly staining and lies at the base of the epithelial layer, not reaching beyond its lower third (Fig. 2). Others, on top of a deeply staining sphere, carry a second sphere of clear cytoplasm, which does not stain with ordinary histological reagents or with silver (Figs. 2 and 3*b*). Other primary sensory cells have a fusiform shape and reach to the free surface of the epithelium, where their outer ends seem to open by a pore (Fig. 3*a*).

There are thus numerous sensory cells of various types in the epithelium which covers the exterior border of the sucker. The number is greatest around the rim of the suckers and decreases passing down the stalk of the infundibulum, and there are few in the skin of the surface of the arm itself. In that region, in fact, the intra-epithelial receptors consist only of a few cells sending their processes directly to the central nerve cord of the arm (Fig. 1).

The processes of the cells in the suckers often run for a considerable distance along the epithelium itself, finally leaving it with a sudden turn (Fig. 2). During this intra-epithelial course the fibre may be provided with one or two collaterals, which branch and form a fine plexus of fibrils. This plexus extends over the whole of the infundibulum and also receives fibres that originate outside the epithelium and reach the plexus after passing through the basal membrane. Probably these fibres, like the similar fibres seen in *Sepia*[5], arise from ganglion cells, but for the moment

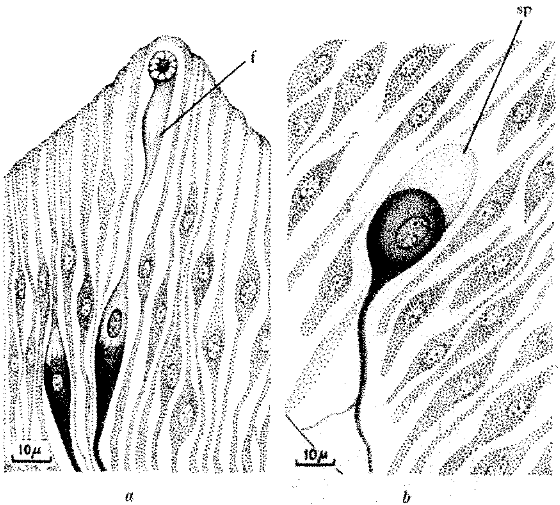

Fig. 3. Lettering as Fig. 2

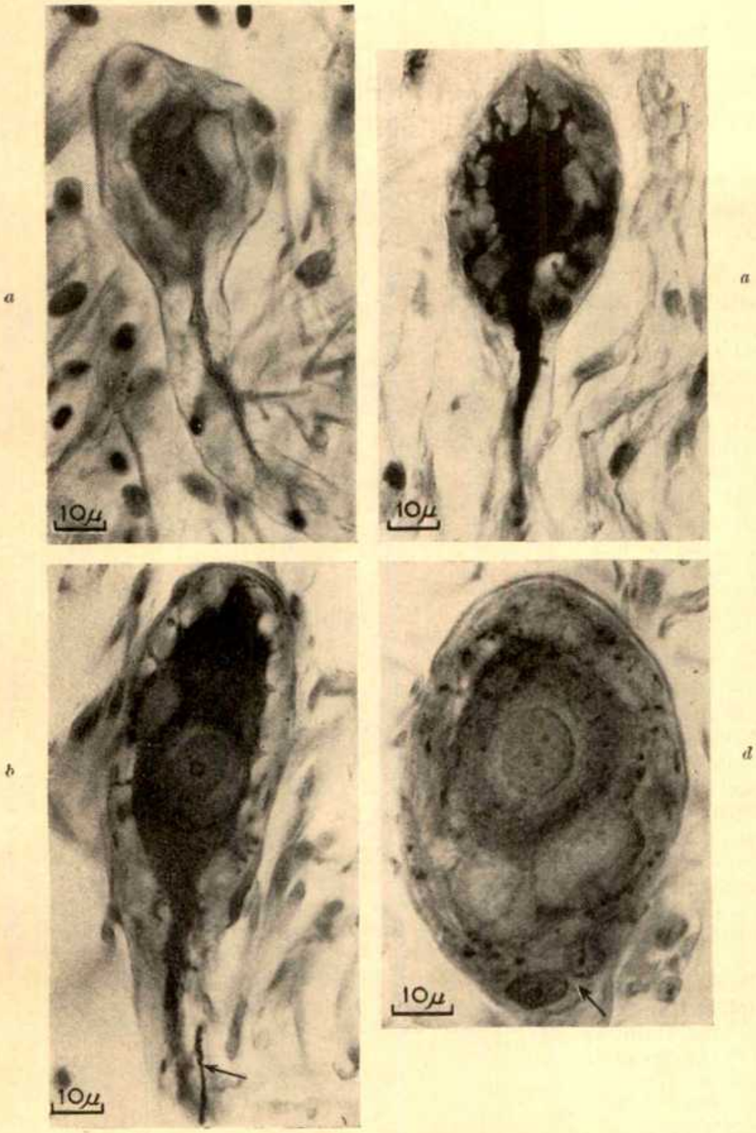

Fig. 4. Encapsulated nerve cell lying in the subepithelial connective of the rim of the sucker in *Octopus*. Bielschowsky–Gros. *a*, Nerve cell with connective tissue capsule surrounding the cell body and axon; *b*, nerve cell with irregular surface and synapsing fibre near the axon (arrow); *c*, nerve cell with stumpy dendritic processes, surrounded by capsule; *d*, nerve cell with vacuoles near the base of the axon (arrow shows nuclei of sheath)

it is not possible to say exactly where these cells are situated.

In addition, these regions contain another type of nervous element, situated more deeply below the epithelium of the sucker. These are ovoid encapsulated nerve cells lying in the sub-epithelial connective tissue at the sides of the muscular walls of the infundibulum (Figs. 2 and 4). These cells, never previously described, show many interesting features. They are numerous in the suckers at the tips of the arms but are less frequent in the large ones near the base. In the larger suckers of 15 mm. diameter, nerve cells reaching 40μ in diameter were found, but in the suckers of 2–3 mm. diameter the comparable cells only reach up to 10μ. The following description refers only to the larger cells. They have an ovoid or globular form and their axon enters the muscles and then leaves them again on the way to the central nerve cord of the arm (Fig. 1). This is not the shortest route, which would run outside the musculature of the sucker.

The nerve cell body and its axon are covered by a nucleated connective tissue capsule. The cytoplasm has numerous vacuoles in its outer region, which are particularly large and numerous at the pole of the cell where the axon arises. The surface of the cells is not smooth but has stumpy dendritic processes. Sometimes these are branched and roughened with ridges, which greatly complicate the appearance of the cell surface. The axon that originates from such cells sometimes shows one or two very fine collaterals. These run among the satellite cells of the sheath that surrounds the axon. It has not been possible to follow these collaterals beyond the entrance of the axon to the sucker musculature. Possibly they run to neighbouring nerve cells.

Around the cell body of each of these cells the silver methods show fine fibres ramifying and branching. These fibres reach the cell from various directions and presumably originate from several sources, including sensory cells of the epithelium (Fig. 2). The character of the fibres when they arrive at the cell, and the fact that some of them originate in the epithelium, suggest that they synapse with the cell. It cannot be excluded, however, from the structure of these cells that they are not themselves receptors.

Thus there is an elaborate receptor apparatus localized in the epithelial covering of the infundibulum and rim of the sucker, indicating that these are areas particularly specialized for receiving stimuli. The conspicuous variety of the shapes of the intra-epithelial receptors provides the possibility for the collection of different sorts of information. In particular, the structure of the cells illustrated in Fig. 3 suggests that there are chemoreceptors as well as tactile receptors in the suckers. The peripheral receptor cells are connected in two ways. There are collaterals in the epithelium and synaptic connexions with nerve cells below the epithelium. The cytological characteristics of these elements and their complicated set of dendrites within a capsule give the impression of a system for the correlation of impulses from various nearby regions.

I thank Prof. J. Z. Young for his help and advice. The work was done at the Stazione Zoologica, Naples, and my thanks are due to Dr. P. Dohrn. Mr. J. Armstrong took the photomicrographs. The work was aided by a grant of the Italian Consiglio Nazionale delle Ricerche.

DISRUPTIVE SELECTION, POLYMORPHISM AND SYMPATRIC SPECIATION

By J. MAYNARD SMITH

Department of Zoology, University College, London

BY disruptive selection is meant selection which favours those members of a population which, in respect of some measurable characteristic, are well above or below the population mean, at the expense of the more typical members of the population. The recent papers by Thoday *et al.*[1-5] have re-aroused interest in the role, earlier discussed by Mather[6], of disruptive selection as an agent which may produce polymorphism and perhaps lead to sympatric speciation. This article discusses the following questions: (1) In what circumstances can disruptive selection maintain a stable polymorphism ? (2) Could such a stable polymorphism be followed by reproductive isolation between the morphs ? (3) Of what situations in wild populations are Thoday's experiments adequate models ?

Consider a pair of alleles A and a at any locus. The familiar genetic basis for a stable polymorphism is that the heterozygote Aa should be fitter than either homozygote. Haldane[7] has recently pointed out that a stable polymorphism can also arise if AA is fitter than aa in one sex, and aa than AA in the other; but this is possible only if the selective advantages are large. Apart from these two cases, stable polymorphism requires that the fitnesses of the various genotypes should be functions of their frequencies in the population. In particular, a stable polymorphism can be maintained if the fitness of particular genotypes increases as their frequency in the population decreases. Batesian mimicry (Mather[6]) and disease resistance (Haldane[8]) are examples of such a situation. If disruptive selection is to maintain a stable polymorphism it must do so by increasing the fitness of genotypes as their frequencies decrease.

If the effects of A, a on the phenotype are additive, then disruptive selection implies that AA and aa are both fitter than Aa; this would certainly not lead to a stable polymorphism, but to a genetically homogeneous population containing only A or only a. But it is possible to imagine a situation in which disruptive selection could lead to a stable polymorphism.

Suppose that the environment is divided up into two or more sub-environments, which, for want of a better word, I shall call 'niches'. Suppose further that the factors responsible for maintaining the population density are such as to ensure that the total density N is made up of n_1 individuals in niche 1 and n_2 individuals in niche 2. In phytophagous insects the niches might be different food plants, in tits they might be nesting boxes and holes in trees, and in man they might be slums and palaces.

Let the relative fitnesses of the various genotypes in the two niches be:

	AA	Aa	aa
Niche 1	$1 + K$	$1 + K'$	1
Niche 2	1	$1 + k'$	$1 + k$

It will be assumed that mating is at random, and that there is no habitat selection (that is, the probability that an individual will live in a particular niche is independent both of the genotype of the individual and of the niche in which it was raised). Then if p is the frequency of allele A among the adults in one generation, the proportions of surviving adults in the two niches in the next generation are:

	Niche 1	Niche 2
AA	$(1 + K)p^2$	p^2
Aa	$(1 + K')2pq$	$(1 + k')2pq$
aa	q^2	$(1 + k)q^2$
Total	$1 + Kp^2 + K'.2pq$	$1 + kq^2 + k'.2pq$

Hence, since the total number of individuals in niche 1 is n_1, the number of AA individuals in niche 1 becomes $n_1(1 + K)p^2/(1 + Kp^2 + K'.2pq)$, and so on. At equilibrium the overall frequency of A in this adult population is p. Consider first the simple case of additive inheritance of fitness in each environment; that is, $K' = \frac{1}{2}K$, $k' = \frac{1}{2}k$. At equilibrium:

$$p = \frac{n_1}{n_1 + n_2} + \frac{n_1K - n_2k}{(n_1 + n_2)Kk} \qquad (1)$$

If an equilibrium is to be possible, p must lie between 0 and 1. This will clearly be the case if $n_1K = n_2k$, so an equilibrium is possible for any values of n_1 and n_2 provided that the selective advantages are nicely adjusted to the sizes of the niches. But if K and k are small, an equilibrium is in practice unlikely. For example, suppose $n_1 = n_2$, the requirement for an equilibrium to exist becomes:

$$\left|\frac{K - k}{Kk}\right| < 1$$

Thus if $K = 0{\cdot}1$ (10 per cent selective advantage), k must lie between 0·09 and 0·11; but if $K = 1$, there will be an equilibrium provided that k is greater than 0·5.

It is easy to show that these equilibria, if they exist, are stable. It can also be shown that similar stable equilibria exist if the alleles show simple dominance, that is, if AA and Aa have the same fitness in both niches.

If in both niches the heterozygote is as fit as the fitter homozygote (that is, $K' = K$, $k' = k$), there will be a stable equilibrium for all positive values of K and k. But this is merely a special case of the familiar phenomenon of a stable polymorphism due to the superior average fitness of the heterozygote. In this particular case the superior fitness arises because the heterozygote is assumed to be adapted to a wider range of environments.

The main conclusion to emerge from this analysis is that disruptive selection can maintain a stable polymorphism in the absence of heterozygous advantage, but will do so only if: (1) the two morphs or extremes are adapted to different ecological niches, and the factors determining the population density are such as to ensure that the numbers of individuals occupying the two niches remain constant or approximately so, (2) the selective advantages are large, or, less plausibly, are by chance nicely adjusted to the relative numbers of individuals in the two niches.

The force of the latter requirement is obvious enough, but the relevance of the former may be made clearer by an entirely hypothetical example of a form of disruptive selection which would not lead to a stable polymorphism. Suppose that predators took predominantly the medium-sized members of a prey population, because the larger members were too big for them to tackle and the smaller members escaped their notice. This would, for the prey species, amount to disruptive selection, but it would lead to a population consisting entirely of large or entirely of small individuals, it could lead to a stable polymorphism only if there were some additional mechanism ensuring that the population contained a fixed number of large individuals and also a fixed number of small individuals. Now in laboratory experiments the selection procedure itself may provide such a mechanism. It will do so if, for example, a fixed number of 'high' and 'low' parents are chosen in each generation. Since the selection pressures in such experiments are usually high, they would be expected to lead to stable polymorphisms. But it is difficult to judge how often the rather severe requirements for an equilibrium will be met in wild populations.

It was assumed here that there was no habitat selection and no assortative mating. Habitat selection can take several forms, it may involve a choice by an individual of its own environment, or of an environment in which to lay its eggs, and in both cases the choice may depend on the genotype of the individual or on the environment in which it was itself raised. Habitat selection of any of these kinds will favour a stable equilibrium, or, to put the same thing in other words, given a degree of habitat selection a wider range of values of K and k will lead to a stable equilibrium. Conversely, given that a stable equilibrium exists, there will be selection in favour of habitat selection.

In discussing the possible role of disruptive selection in sympatric speciation, the vital question is the relation between disruptive selection and assortative mating. There are in fact two questions first, given that there is a degree of assortative mating, will this favour the establishment of stable polymorphism ?, and secondly, given that a stable polymorphism exists, will selection favour assortative mating ? The answer to both these questions is in the negative unless, because of habitat selection or for other reasons, the mean fitness of heterozygotes is less than that of homozygotes.

Consider first the effect of assortative mating on the stability of the equilibrium. Assuming that assortative mating is complete, then only AA and aa individuals will exist. If the fitnesses in the two niches are as given here, then p, the overall frequency of AA individuals, is given by equation (1), in other words, assortative mating does not alter the requirements for an equilibrium. Since complete assortative mating corresponds to the case of two sympatric species, it may seem surprising that the requirements for coexistence are so severe. But the requirements would in fact be severe in the absence of habitat selection.

Consider now selection in favour of assortative mating, again in the absence of habitat selection. At equilibrium, both for additive inheritance and for simple dominance, the average fitnesses of the three genotypes are equal, consequently the number of progeny left by an individual is unaffected by the genotype of its mate, and so there will be no selection favouring assortative mating. But if there is habitat selection, the mean fitness of the homozygotes will be greater than of the heterozygotes, and there will be selection for assortative mating. Therefore, if polymorphism based on disruptive selection is ever the first step in sympatric speciation, it seems likely that the next phase would be the evolution of some degree of habitat selection, and only then would reproductive isolation arise.

Yet Thoday and Gibson[5], in an experiment in which only flies with the highest and the lowest numbers of bristles were used as parents, observed the establishment of reproductive isolation between the two groups with what they themselves describe as remarkable rapidity. It is indeed difficult to understand the rate of the response they obtained, in view of the comparatively slow progress achieved by other workers[9] selecting for reproductive isolation between mutant strains of *Drosophila*. But leaving aside the rate of response, the system investigated by Thoday and Gibson was one in which there might well be selection for assortative mating. The conclusion reached here that there would be no selection for assortative mating was based on the assumption that in each niche the inheritance of fitness was either additive, or showed simple dominance, the heterozygote always resembling the same homozygote. But if selection is sufficiently intense, it is possible that the fitness of the heterozygote will, in both environments, equal that of the less fit homozygote. For example, suppose that bristle number is determined by only a single pair of alleles. Then it might be that all individuals selected as 'high' would be AA, and all selected as 'low' would be aa, if so, the heterozygotes would have zero fitness, and there would be selection for reproductive isolation.

Thus if the experiment of Thoday and Gibson is a model of a situation which might arise in Nature, it is of a situation in which (1) there is some mechanism ensuring that the extreme forms shall occur in equal numbers, or at least in numbers bearing a fixed relation to each other, (2) the mean fitness of heterozygotes is lower than of homozygotes.

These requirements would be met by the two-allele situation investigated in this paper if in each niche the heterozygote had a fitness equal to the less fit homozygote, that is, if $K' = k' = 0$.

Then at equilibrium

$$\frac{n_1 K p}{1 + K p^2} = \frac{n_2 k q}{1 + k q^2} \qquad (2)$$

This equation is algebraically intractable. But clearly if $n_1 = n_2$ and $K = k$, an equilibrium exists when $p = q = \frac{1}{2}$. Is this equilibrium stable ? If p_{x+1} and p_x are the frequencies of A in two successive generations, then

$$p_{x+1} - p_x = \tfrac{1}{2} p_x q_x \left\{ \frac{K p_x}{1 + K p_x^2} - \frac{K q_x}{1 + K q_x^2} \right\}$$

and considering a small displacement from equilibrium, $p_x = \frac{1}{2} + \Delta p$ where Δp is small

$$p_{x+1} - p_x = \frac{K}{4 + K}\left(1 - \frac{2K}{4 + K}\right)\Delta p \qquad (3)$$

For stability, $p_{x+1} - p_x$ must be negative when Δp is positive. From equation (3) it follows that the equilibrium is unstable for $K < 4$ and stable for $K > 4$. In other words, if reproductive isolation is to be a consequence of disruptive selection, then the fitness of heterozygotes must be low if selection is to favour assortative mating, and this in turn requires that the intensity of disruptive selection must be very high if a stable polymorphism is to be maintained for long enough for isolating selection to operate.

In conclusion, it seems that if disruptive selection is to lead to stable polymorphism, and *a fortiori* if it is to lead to reproductive isolation, the conditions which must be satisfied are severe. But they are of a kind which may often be satisfied in laboratory experiments, and which may perhaps sometimes be met with in Nature.

EXPERIMENTAL VARIABILITY IN *FUSARIUM MONILIFORME* SHELD. LEADING TO THE FORMATION OF GIBBERELLINS

By Prof. A. A. IMSHENETSKI and O. M. ULIANOWA

Institute of Microbiology, Academy of Sciences, Moscow, U.S.S.R.

FROM year to year micro-organisms thriving under natural conditions continually reveal new physiological features. Recently, numerous investigators have paid attention to the gibberellins. The wide range of tests with gibberellins proves that this group is finding a broad field of practical application, for example, in grape cultivation and in floriculture.

Hence, it was of interest to learn whether mutations can be induced in *Fusarium moniliforme* experimentally, and to explore whether the mutations produced reveal higher activity than the initial wild culture of this fungus. Theoretically, this possibility seems quite feasible owing to the fact that the gibberellins do not belong to the basic products and the formation of the latter is not related to the energy metabolism of the micro-organism. Similar to the antibiotics and other physiologically active substances, gibberellins are produced in comparatively small quantities and their biosynthesis has no direct relation to the energy supply processes.

The experimental material selected was cultures of *Fusarium moniliforme* Sheld. A suspension of fungal conidia filtered through a sterile plankton net and containing 7 million conidia per 1 ml. of sterile water was irradiated with bactericide lamps of the *BUV*-15 type which emits primarily rays with a wave-length of 2537 Å. The time of exposure varied from 1 to 20 min., and this corresponded to the quantity of radiation energy ranging from 1,800 ergs/mm^2 to 36,000 ergs/mm^2. The water-suspension of irradiated or non-irradiated conidia was plated on potato or Czapek glucose agar. An inoculation of different nutrient media was made from each colony grown after the inoculation of the exposed material irrespective of whether the colony in its external appearance was like the colony of the initial culture or strongly different from it.

The cultivation of the initial *Fusarium* and various ultra-violet mutants of it was carried out on several solid and fluid media. The solid media were potato agar, Czapek glucose agar, agarized Raulin–Thom medium, Stodola agarized medium in which ammonium chlorate was substituted by sodium nitrate and malt agar 7° Balg. The liquid media were Stodola medium with an addition of trace elements according to the method of Lilly and Barnett, Raulin–Thom medium with trace elements and Darken medium.

To test the ability of *Fusarium* to form gibberellins, yeast autolysate, milk hydrolysate and a solution of glutamic acid were added to liquid media. The quantitative determination of gibberellins was carried out according to the Muromtsev and Nestjuk colorimetric method. Other biological tests were also applied.

Exposure of the initial *Fusarium* culture to various ultra-violet doses showed first of all that increasing the exposure results in an abrupt decline of the number of colonies growing from the exposed conidia. If the inoculation of the non-irradiated (control) conidia on to the potato agar led to the development of 4,400 (100 per cent) colonies, only 100 (2.3 per cent) developed after exposure to 30,600 ergs/mm^2. The conidia of one particular strain of *Fusarium* proved to be resistant to the effect of the ultra-violet rays and the application of relatively large doses of irradiation equal to 36,000 ergs/mm^2 revealed 0.45 per cent of viable conidia.

120 ultra-violet mutants were obtained altogether, most of them exhibited changed morphological and physiological peculiarities. All mutants obtained when grown on solid media formed colonies of smaller size than of the initial culture. This difference in the size of colony was especially great on potato agar and was less pronounced on other solid nutrient media. Moreover, most of the mutants differed from the initial culture in having a shorter aerial mycelium, a less fluffy surface to the colonies, more acutely pronounced folded pattern of growth, a changed shape of the colonies and different colour of the aerial and substrate mycelia.

For example, on Czapek agar the colonies of the initial strain were white with a slight lemon-yellow shade, whereas the colonies of active variants 3_6 and 5_6 were shaded pink and lilac. Apart from the Czapek agar the change of shape and coloration in colonies was distinctly revealed on malt-agar on Raulin–Thom agarized media and on Thom media, it was less pronounced on potato agar. The liquid nutrient media revealed a changed pattern in the growth of films and change of colour in the culture liquid of most variants.

Table 1. Formation of Gibberellins by the Mutants of *Fusarium moniliforme*

Groups of ultra-violet mutants	Activity of mutants	No of ultra-violet mutants	Per cent of the total No of ultra-violet mutants	Doses by which the mutants were produced (ergs/mm ²)
1	Exceeding the initial	2	1 7	5,400 (600)*
2	Equal to the initial strain	35	29 1	at all doses of 900–32,400
3	Less than initial	78	65 0	mainly 23,400–25,200 and higher
4	Complete loss of activity	5	4 1	30,600–36,000

* Recurrent dose irradiation is indicated in brackets.

The action of large doses of ultra-violet rays led to the formation of variants with little pronounced fluffiness in colonies and these cultures produced 'bare' leathery films at the top surface of liquid media, these films resembled bacterial films

The ultra-violet doses equal to 21,000–25,000 ergs/mm ² led to the formation of mutants which produce sporodochia and pionnotes in great numbers, this may be ascribed to a considerable change in metabolisms The initial fungal culture has never produced any similar formation in any of the media tested Microscopic examination of the mutant preparations has also revealed several changes in the shape and size of the macro- and micro-conidia and in the mycelium threads

The results presented in Table 1 show that the 120 mutants can be subdivided into four groups in accordance with their ability to produce active gibberellin-like substances

Formation of gibberellin in the *Fusarium* cultures developed very slowly, therefore we examined the dynamics of its accumulation in the cultures of the initial strain and in some of the mutants (Fig 1) Experiments have shown that active variants 3_6 and 5_6 produced a somewhat greater amount of gibberellin than the initial culture and that an acceleration of gibberellin biosynthesis was observed in mutants 12_1, 3_6 and 5_6 since the latter formed a maximum quantity of gibberellin 5–7 days before it was noticeable in the control strain In more active mutants the constructive metabolism was somewhat upset, and they accumulated a biomass which was considerably less than that of the control strain However, their ability to synthesize gibberellin exhibited a sharp increase, and 1 5–3 times more gibberellin was produced per unit dry weight These changes in the physiological features of the mutants most probably support the hypothesis that the production of gibberellin is not related to the metabolism and appears to be a 'by-synthesis', and in ultra-violet mutants this process may be intensified

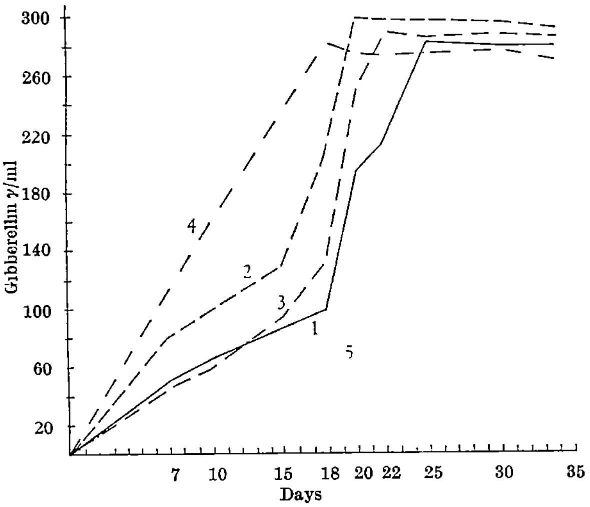

Fig 1. Formation of gibberellin in the initial strain of *Fusarium* and in mutants 5_6, 3_6, 12_1 and 16_1 in Stodola medium with 3 per cent glucose, trace elements and glutamic acid
1, initial strain, 2, mutant 5_6, 3, mutant 3_6, 4, mutant 12_1, 5, mutant 16_1

Active variants, as compared with the initial culture, consumed glucose at a greater rate, this resulted in a more rapid decrease in *p*H of the medium Less citric and gluconic acids and more acetic acid and ethyl alcohol were produced (Table 2) Consequently, the metabolism in those mutants was subjected to similar changes, it should be emphasized that the reduced product, that is, the ethyl alcohol, was being formed more intensively

Table 2 Production of Organic Acids and Alcohol in the Initial *Fusarium* Strain and in Ultra-Violet Mutants (Time of Experiments, 25 Days)

Compound	Amount in mgm /200 ml medium The initial strain	Mutant 3_6	Mutant 5_6	Mutant 12_1
Citric acid	984 57	804 75	645 35	769 5
Gluconic acid	474 24	437 76	414 96	383 04
Oxalic acid	0	0	0	0
Acetic acid	160 0	175 0	220 0	237 5
Ethyl alcohol	75 90	100 67	158 7	104 65
Malic acid and succinic acid (qualitative reactions)	present	present		present

The physiological effect produced by the filtrate of the cultural media of active variants of *Fusarium* on the growth and development of different higher plants has shown that it has a stronger stimulating effect on the growth of shoot and root than the cultural filtrate of the initial strain

The dwarf peas (varieties De Grass and Pioneer) responded strongly to the action of gibberellin and attained the height of common peas under the influence of stimulators A distinctly pronounced stimulating effect was observed in the surface parts of plants when the latter were treated with cultural liquid of the active mutants This accelerating influence was noted in corn, cucumbers, garden peas, soya beans, but it was less pronounced in barley, oat, rye and wheat In dwarf peas and lettuce the lengths of the roots increased 2–3 times under the effect of the cultural filtrate of the active variants as compared with the initial strain

The stimulation of shoots and roots developed along with the intensification of the synthetic processes, owing to this the dry weight of plants treated with cultural filtrate of active mutants was higher A greater increase in dry weight was observed in plants which failed to reveal considerable elongation Excessive 'gigantism' in plants under the influence of stimulators sometimes exhibited a pathological condition, in this case the dry weight of the plant was sometimes even lower than that of control plants In our experiments the dry weight of peas, cucumbers and soya increased relatively more than in other plants

The stimulating effect of the mutant strain cultural filtrate cannot be ascribed solely to the action of gibberellin present in the fluid The formation of this stimulant in the mutant cultures is not solely responsible for the considerable difference observed in the action of the cultural filtrate of the initial strain Most probably, the mutants have developed and intensified the biosynthesis of other substances formed by *Fusarium* and stimulating plant growth.

RADIOPHYSICS

Very-Low-Frequency Discrete Emissions received at Conjugate Points

In a recent article[1] describing a geomagnetic conjugate point experiment an accurately synchronized pair of spectrograms was shown. As shown in Fig. 1 of that article a sequence of six noise bursts in the 5–6 kc./s. frequency region was observed at both Knob Lake, Canada (68° N., geomagnetic), and at Byrd Station, Antarctica (70° S., geomagnetic), but the sequence began at Knob Lake 0.8 ± 0.1 sec. before it began at Byrd.

However, close inspection of Fig. 1 indicates that in each case the sequence is not six separate bursts but a pair of bursts seen three times. In support of this it will be noticed that the shapes and separation of the two bursts in each pair are similar and in each case the first burst occurs at a slightly higher frequency than the second. Furthermore, the time separation between successive pairs (using the time-scale provided) is 1.6 ± 0.1 sec., which is just twice the delay between Knob Lake and Byrd. Thus at intervals of 0.8 sec. this pair of bursts appeared alternately at Knob Lake and Byrd.

This phenomenon cannot be due to successive reflexions in opposite hemispheres of electromagnetic energy because the observed time delays are too short. Whistler observations in these latitudes show 5 kc./s. propagation times between 1.5 and 2.5 sec. for a single hemisphere to hemisphere trip[1]. Even then these times refer to lower latitudes because geomagnetic field lines terminating at latitudes greater than about 62° do not allow 5 kc./s. propagation of this type[2]. Thus if this phenomenon were due to whistler type echoes the delays would be several times longer.

However, such a sequence of alternate reception at conjugate points was predicted in a theory proposed by me[3] for the production of very-low-frequency discrete emissions. In fact such a conjugate point experiment was suggested as a test for the theory.

According to this theory Doppler-shifted cyclotron radiation is emitted by a small cloud or bunch of electrons spiralling along a field line. Only the downward-shifted frequency can propagate so that radiation is only emitted backwards. If the bunch should survive several trips along the field line from hemisphere to hemisphere, being reflected at the ends by magnetic mirror effect, then an observer at each end of the field line would receive an emission each time the bunch was travelling away from him. Thus for each observer the time between successive emissions would be the complete (there and back) oscillation period of the cloud and the delay between the sequences observed in opposite hemispheres would be half this period[3].

The complete oscillation period of 1.6 sec. from Fig. 1 (ref. 1) would correspond to 60 keV. electrons (for minimum helical pitch angles of 20°) if the guiding field line was that connecting the two observing stations or 15 keV. electrons if the guiding field line was typical of those (around 60°) producing nose whistlers observed at Byrd[2]. These electron energies deduced from the oscillation period (15–60 keV.) are close to those (5–25 keV.) required by my theory to produce the detailed frequency-time shape of observed discrete emissions[3].

I thank Prof. G. R. A. Ellis, of the Physics Department, University of Tasmania, for advice.

[2] Smith, R. L., *The Use of Nose Whistlers in the Study of the Outer Ionosphere* (Stanford Electronics Laboratory, 1960).

[3] Dowden, R. L., *J. Geophys. Res.*, 67, 1745 (1962).

Dowden suggests that the six bursts of noise shown in Fig. 1 of our article consist of a pair of bursts seen three times at each end of the path, and that this interpretation provides support for a new theory of very-low-frequency emissions which he has published elsewhere.

We agree that this interpretation is entirely consistent with the data reported in our article. As a matter of fact, further study of the original tape recordings has shown additional noise bursts which can be fitted into a repetitive or echo pattern, in which the phase is opposite at the two ends of the path. The echoing of noise bursts between stations in opposite hemispheres is a common occurrence, and is the subject of a detailed study now in progress at the Radioscience Laboratory, Stanford University. Results of this work will be reported in the near future.

Although we can support the 'echo' interpretation of Fig. 1, we question Dowden's conclusion that the phenomenon cannot be due to successive reflexions in opposite hemispheres of electro-magnetic energy travelling in the whistler mode. His argument is based on the fact that whistler observations at these latitudes show 5 kc./s. propagation times between 1.5 and 2.5 sec. for a single hemisphere-to-hemisphere trip (one-hop), while the observed one-hop delay of the noise bursts is only 0.8 sec. (one-half of observed period of 1.6 sec.). It is implied that both the path of propagation and the electron density in the magnetosphere are about the same in the two cases. Neither of these assumptions is justified, as we shall see.

Whistler-mode path latitude bears little relation to the latitude of the receiving station. For example, data analysed by Smith[1] show a variation in the nose frequency (closely related to path latitude) at Byrd from 4.5 kc./s. to 12 kc./s. For the model of electron density derived by Smith, the corresponding minimum gyro-frequencies at the top of the path are about 11.2 kc./s. and 30 kc./s., respectively. The corresponding effective geomagnetic latitudes are 61° and 55°, respectively. Other data show that even lower latitude paths are often observed at Byrd Station[2].

Another factor affecting propagation time is the electron density along the path of propagation. Carpenter has shown that electron densities are often markedly depressed during magnetic storms[2]. One-hop delays at 5 kc /s can drop as low or lower than 0 8 sec at Byrd following the onset of a magnetic storm The record in question was obtained on the day following a magnetic disturbance in which the 3-hr K_p index reached a maximum of 6 Thus it is quite possible that the delays observed are in fact consistent with the whistler-mode interpretation

The fact that we cannot rule out the whistler-mode echo explanation does not, of course, disprove Dowden's hypothesis that the noise bursts were generated by bunches of electrons bouncing back and forth between magnetic mirror points Our comments are intended only to suggest the inherent complexity of the problem and the need for more complete data on the relationship between whistler-mode propagation and very-low-frequency emissions

GEOPHYSICS

Age of the Earth's Crust and Lead Model Ages

OVER the past few years the observed time-dependence of the isotopic composition of lead in ore deposits has been used in attempts to estimate a 'model age' for each deposit In the main, two general lines of attack appear to have been used On one hand Canadian writers[1] have adopted a simple model, with a single growth curve, the parameters of which have been determined empirically; whereas the European workers[2] have set up models which allow for a greater variety of relative abundances of uranium–lead–thorium in the parent material, and where the parameters are physical constants which can be determined by independent methods These two methods of attack have seemed to give different values of the age, and the further suggestion has recently been made[2] that the two models furnish very different values for the age of vein deposits

In calculations which I have carried out in connexion with some results to be published elsewhere, I have shown that the major part of the discrepancy in model ages obtained by the two methods rests on the value of t_0, the 'age of the earth's crust'

In the Holmes–Houtermans equation (2)

$$\frac{y - y_0}{x - x_0} = \frac{1}{137\ 8} \times \frac{e^{\lambda_2 t_0} - e^{\lambda_2 t}}{e^{\lambda_1 t_0} - e^{\lambda_1 t}}$$

where x, y, are the ratios $^{206}Pb/^{204}Pb$, $^{207}Pb/^{204}Pb$ for the sample, x_0, y_0, the corresponding values for 'primordial lead' (average of Patterson's[3] values for Canyon Diabolo and Henbury troilite leads), and λ_1, λ_2, the decay constants for ^{238}U, ^{235}U (ref 4), three values now used of t_0 have yielded three very different values for the model age calculated for the one (x, y) (Table 1)

Table 1

t_0 × 10^9 yr	4 50 (ref 2)	4 510 (ref 1)	4 550 (ref 3)
age × 10^6 yr	1669	1640	1524

These compare with a value 1,524 million yr for t_{6-7} of Russell and Farquhar[1], whose empirical equation yields an independent value for t_0 = 4 56 × 10^9 yr Over quite a variety of specimens from Precambrian localities, which range from 'conformable' leads through vein deposits to those distinctly anomalous, close agreement has been obtained between the t_{6-7} model age and that calculated according to the Holmes–Houtermans model, using $t_0 = 4\ 55 \times 10^9$ yr , with the standard deviation of the ages of a set of comparable specimens slightly less in the first case than in the second

Thus it would seem that both models yield very similar conclusions, and that any discordance which has appeared in the past has resided almost entirely in the value chosen for t_0 The large error magnification exhibited here would appear to be an inevitable consequence of the exponential function used in all lead calculations, of which the equation quoted is a typical example Where t_0–t (or in the general case t_1–t_2) is small, this magnification should prove to be less than unity, which is perhaps one reason why this effect has not been remarked on previously

PHYSICS

Direct Conversion of Fission Heat to Electric Power

EXPERIMENTS have been performed in the reactor *Pluto* as a stage in the development of cæsium-neutralized diodes for the direct conversion of fission heat to electric power This work is similar to that being carried out in the United States, and the first fission-operated diode was reported by Grover at Los Alamos in 1959[1] Due to its greater cathode area, the present device has produced a larger value of output current than hitherto reported and incorporates a number of new features Measurements were made with two rigs, the object being to test the fuel rod material and method of mounting, to determine temperature distributions and heat transfer data and to study the performance of the diodes as generators

Each diode (Fig 1) contained a cylindrical cathode of UC/ZrC solid solution brazed to a tantalum support, and a stainless-steel anode which was extended to form a catchpot and a cæsium reservoir The radial spacing between cathode and anode was 0 5 cm In this intermediate design the emission current circulated via the extended anode casing and cathode support, so that a ceramic/metal insulating seal was not required The output was determined by monitoring the voltage across the extended anode casing above the ceramic spacer The cathodes were 5 7 cm long and 1 0 cm in diameter, enriched to contain 8 3 gm uranium-235 over the lower 3 0 cm , the remainder containing natural uranium The composition of the UC/ZrC was 45/55 mol per cent with a melting point more than 3,000° C Cathode temperatures were monitored by means of a W/WRe, beryllium oxide insulated, tantalum sheathed thermocouple situated at the junction of the natural and enriched material Other thermocouples of chromel/

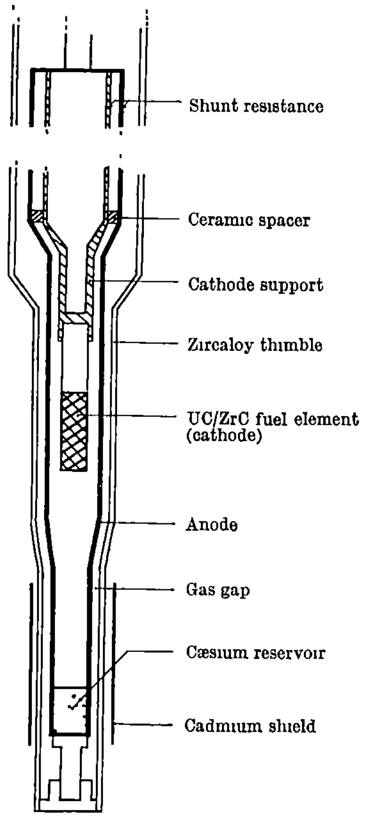

Fig 1 Inpile diode (first rig)

alumel measured the temperature distributions over the catchpot, casing and cathode support

The catchpot was designed to hold the cathode in the event of its failure by fracture or melting It was lined with tantalum and also contained a tantalum thimble located over the cæsium capsule The catchpot region was shielded by a stainless-steel sheathed cadmium cylinder which reduced the neutron flux in this region to about 5 per cent of the undisturbed value Cæsium was inserted in a sealed silica capsule which was burst by heating to about 200° C after the chamber had been sealed

A concentric zircaloy thimble surrounded the anode with a nominal gas gap of 0.010 in containing helium The bulk of the anode heat was transferred to the reactor heavy water flow through the helium gas gap and the zircaloy thimble

In the first rig (Fig 1) the temperature of the cæsium was controlled in conjunction with the anode surface temperature by varying the pressure of helium in the gas gap between the limits of 1 atmosphere and 8 torr Thus, in this case, the cæsium vapour pressure and the collector surface temperature varied together In the second rig the cæsium reservoir was surrounded with a 250-W 'Pyrotenax' heater (not shown in Fig 1) which yielded some measure of independence in cæsium vapour pressure and anode temperature

The highest value of current achieved with the first (variable gas pressure) rig was 140 amp (14 amp / cm ^{2}) when the voltage across the load was 0.3 V The corresponding cathode and anode temperatures were about 2,100° C and 687° C respectively and the cæsium vapour pressure 0.1 torr This output of 42 W was obtained at an efficiency of about 3 per cent Similar results were obtained from the second rig

The first rig yielded the above output after a life-test of 38 hr operation time with cathode temperatures in the region of 1,950° C and the output currents of about 70 amp During this test there was no clear evidence of any decrease in performance

In this intermediate design the current was not fed to a matched load, and furthermore not all the output voltage appeared across the load An allowance for these effects would lead to an efficiency in the 5–10 per cent range

Quasi-Trapping of Low-Energy Electrons in Water Vapour

The interaction of low-energy (less than 1 eV) electrons with water vapour has been examined by means of a swarm method[1-3] in which water vapour at pressure f_1p was added to ethylene, carbon dioxide and methane, at pressures f_2p It was found that when f_1p ranged from 1 to 16 mm mercury, and f_2p was of the order of 100–200 mm mercury, no electron capture occurred for an E/P [V cm $^{-1}$ (mm mercury)$^{-1}$] ranging from 0.01 to 4.0 (An exception must be made for the case of water–carbon dioxide where a very small capture cross-section was observed and may be due to the formation of carbonic acid) However, an interesting and significant increase in the electron transport time was observed and is illustrated in Fig 1 for mixtures of water and ethylene In Fig 1, w^{-1} is the transport time per cm of travel in the field direction, and it is observed that (1) w^{-1} increases linearly with the ratio f_1/f_2, (2) w^{-1} is independent of the total pressure p for the range 100–400 mm mercury These results suggest that electrons make collisions of long duration with water and that the lifetime of the 'quasi-trap' $[H_2O]^-$ is limited by collision with ethylene for the pressure-ranges already quoted

The notion of long-duration collisions suggests immediately that the observations by Bradbury and Tatel[4] of electron capture in pure water vapour can be interpreted in terms of the formation of electron traps, that is, successive collisions of quasi-traps with water molecules to form $(H_2O)_n^-$, where n, the number of water molecules in the negatively charged cluster, becomes of such magnitude that electrons become permanently trapped by polarization forces The existence of such local self-consistent quantum states has been shown to be theoretically possible by Pekar[5] in the case of ionic crystals, and these states (polarons) have, in fact, been invoked for the case of

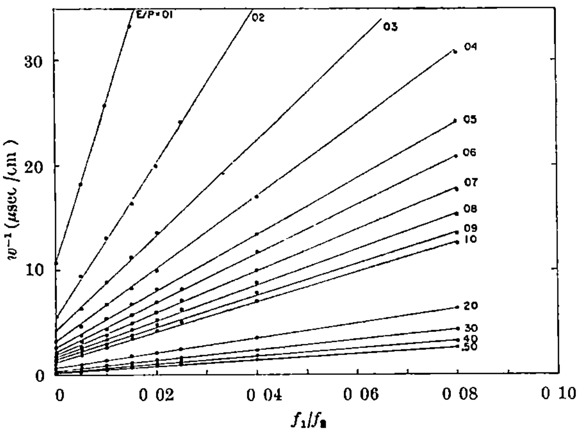

Fig. 1. Electron transport time per cm , w^{-1}, for mixtures of water (mole fraction f_1) and ethylene (mole fraction f_2) versus f_1/f_2 for various values of E/P

low-energy electron trapping in liquid water by Weiss[6] The present ideas of quasi-traps are not in contradiction with the fact that $[H_2O]^-$ has not been observed in mass spectrometers, since the lifetime of an isolated $[H_2O]^-$ may be much shorter than the flight time (typically 10^{-6} sec) in a mass spectrometer The 'polaron' would, of course not be observed in the mass spectrometer since the vapour pressure is too low to permit its formation Thus the simple mechanism discussed here suffices to interpret four sets of observations, that is (1) our observation that electrons are not captured when the pressure of ethylene is about 100 mm mercury, (2) our observation of increased transport time (Fig 1), (3) the observations of an increasing capture cross-section with increasing pressure of pure water made by Bradbury and Tatel, (4) the failure to observe $[H_2O]^-$ in the mass spectrometer

The nature of the force involved in the primary collision process is thought to be that of an electron-permanent electrical dipole interaction for the following reasons (1) when other molecules having permanent electrical dipoles are substituted for water, an effect similar to that in Fig 1 is observed, while little correlation is found when molecules merely having large polarizabilities are substituted, (2) at distances r greater than 3 Å , the energy of interaction of an electron with the permanent dipole of water is considerably greater than its energy of interaction with the induced dipole in water , (3) the slope of the curves in Fig 1, $S(E/P)$, can be accounted for when a v^{-2} cross-section (associated with the r^{-2} interaction energy of a permanent dipole) is assumed, and cannot be accounted for when a v^{-1} cross-section (corresponding to the r^{-4} interaction energy of an induced dipole) is assumed

We wish to emphasize some essential differences in the quasi-trap, $[H_2O]^-$, and the 'polaron' The quasi-trap, $[H_2O]^-$ (1) results from the trapping of an electron by a single molecule, (2) has a limited lifetime (for example, 10^{-8}–10^{-7} sec) which is governed by a statistical process in which some kinetic energy of interaction is transferred to an internal degree of freedom (for example, vibration or rotation) On the other hand, the polaron (1) results from the interaction of an electron with a group of polarizable molecules, (2) a stationary quantum state is formed Thus, the quasi-trap, according to earlier comments on the observations of Bradbury and Tatel, may grow into a polaron by further interaction with polarizable molecules

Re-entrant Motion in Special Relativity

Consider two inertial co-ordinate systems, S and S^*, such that S^* moves relatively to S along the direction of their coincident x-axes at the constant speed $v = \lim_{\Delta x\to 0} (\Delta x/\Delta t) = \lim_{\Delta x^*\to 0} (-\Delta x^*/\Delta t^*)$ The Lorentz transformation requires that, for any two events characterized by separations $(\Delta x, \Delta t)$ in S and by $(\Delta x^*, \Delta t^*)$ in S^*

$$\Delta x^* = \frac{\Delta x - v\Delta t}{\sqrt{1 - v^2/c^2}} \qquad (1)$$

Consider an idealized, thin, circular, disk of radius r, made of infinitely strong material, rotating with uniform angular velocity ω relative to the laboratory system S about a fixed axis through the centre and perpendicular to the plane of the disk It is sometimes thought in such a case that the edge speed is $v = r\omega$ It is shown here that this is true only as an approximation, valid for small v, and that in fact $r\omega$ can exceed c, the speed of light, while v can never do so

We suppose the outer edge of the disk to be marked with numerous point-markers that divide it into n equal segments (Alternatively, the circular disk might be replaced by an n-sided regular polygon) If n is very large the segment rest-length, s_0, will be very nearly equal to $2\pi r/n$, and this approximation will become exact as $n \to \infty$ Consider S^* to be the Lorentz frame in which a particular edge-segment of the disk is momentarily (approximately) at rest as the segment passes a nearby fiducial point in the laboratory system S Let the two events with respect to which the increments $(\Delta x, \Delta t)$ in S and $(\Delta x^*, \Delta t^*)$ in S^* are defined be the passages opposite the fiducial point in S of the two adjacent point-markers on the disk-edge that delimit the segment in question Then $\Delta x = 0$ and $\Delta x^* = s_0 = 2\pi r/n$ Also, $\Delta t = T/n$ where $T = 2\pi/\omega$ is the rotation period of the disk, as measured in S (This is merely the assertion that n segments pass the fiducial point in S in n times the time required for one segment to pass it) Using these values of Δx Δx^*, and Δt in equation (1), we obtain

$$\frac{2\pi r}{n} = \frac{-vT}{n\sqrt{1 - \frac{v^2}{c^2}}}$$

Hence,

$$\frac{2\pi r}{T} = r\omega = \frac{-v}{\sqrt{1 - \frac{v^2}{c^2}}} \qquad (2)$$

Squaring, we have

$$r^2\omega^2 = \frac{v^2}{1 - \frac{v^2}{c^2}}$$

or

$$v = (\pm)\frac{r\omega}{\sqrt{1 + \frac{r^2\omega^2}{c^2}}} \qquad (3)$$

Thus, $|v|$ is always less than c, no matter what the value of $r\omega$ may be. The approximation $|v| = r\omega$ is valid only for $r^2\omega^2 \ll c^2$. No physical restriction is placed by special relativity on the value $r\omega$. This conclusion contrasts sharply with the usual[1] supposition that $r\omega < c$ is a requirement of relativity.

More generally, if a 'round-trip speed' $v_{r\,t}$ for the re-entrant motion is introduced via the definition $|v_{r\,t}| = r\omega = 2\pi r/T =$ (distance travelled) / (round-trip time), then the instantaneous speed v, which must be used in the equations of the Lorentz transformation, is related to this round-trip speed by

$$v = \frac{v_{r\,t}}{\sqrt{1 + (v_{r\,t})^2/c^2}} \qquad (4)$$

In classical physics, of course, the round-trip speed (for uniform motion) is not conceptually distinguished from the instantaneous speed, although it is always operationally distinguishable.

Discussion of the numerous surprising implications of this result for all types of re-entrant motion, including the 'twin paradox' (from equation (2), $v_{r\,t} = v/\sqrt{1 - v^2/c^2}$, hence, $v_{r\,t}$ appears anomalously fast by the factor $(1 - v^2/c^2)^{-1/2}$, this just compensates the time-dilatation 'staying young' of the space traveller by the same factor, so that the twins age the same (both 'stay young')), and for the nature of space-time (for example, because of the equal ageing, independently of motion, just mentioned, one may postulate that the proper-time increment $d\tau$ is an exact differential, dt inexact; in this case Fermat's principle, $\delta \int dt = 0$, describes the motion of both material particles and photons; and space-proper-time, rather than Minkowski space, is the appropriate 4-space for physical description), had best be deferred until the validity of the present derivation is confirmed. It may be objected that special relativity should be viewed as incapable of treating any sort of accelerated motion. However, Pauli in his well-known work on special relativity[2] indicates that the subject is founded not on the ignoring of acceleration but on the explicit assumption that acceleration produces no specific effect on relativistic kinematics. Such an assumption has recently received impressive experimental confirmation[3] for accelerations up to $10^{16}g$. Therefore the burden of proof would seem at present to rest on those who believe that special relativity is entirely inapplicable to re-entrant motion.

CRYSTALLOGRAPHY

The C–H ... O Hydrogen Bond in Crystals

Over the past ten years, numerous examples of 'short' intermolecular distances between a carbon atom with at least one hydrogen atom attached to it and an oxygen atom have appeared in papers on the crystal structures of organic molecules. By 'short' it is meant that the intermolecular distance is considerably less than the sum of the van der Waals radii for the atoms or groups concerned. In practically all cases, the significance of these interactions has not been noted.

The most electronegative of the atoms can take part in hydrogen bonding. Fluorine, oxygen, nitrogen, chlorine and bromine all form hydrogen bonds of different strength, the strongest ones being associated with fluorine, the most electronegative element. The hydrogen atom is located between the two electronegative atoms, and the bond formed by these three is thought to be linear or nearly so. The number of compounds containing hydrogen bonds, in which the positions of the hydrogen atoms are accurately known, is comparatively small. It is usually assumed that the deviation from linearity (the angle H–A ... A′ between the direction of the hydrogen atom A–H and the direction of the hydrogen bond A ... A′) is not greater than 15°. Recently, Hamilton[1] has shown in a neutron diffraction study of dimethylglyoxime that this angle is as much as 24°. The angle O–H ... N is 140 ± 3°, a value significantly different from 180°. The hydrogen bond is therefore not necessarily linear.

The C–H group may be activated by other atoms or groups of atoms promoting ionization or partial ionization of the hydrogen atom. Under these conditions, it resembles the O–H and N–H groups, etc., and it may form hydrogen bonds. As an example, chloroform in which activation of the C–H group by the chlorine atoms occurs will hydrogen bond with strong bases like pyridine and triethylamine. In the crystalline state, hydrogen cyanide at −120° and −80° consists of molecules arranged in infinite chains with 'short' carbon–nitrogen distances of 3.18° along the C–H ... N directions[2]. These were assumed to be hydrogen bonds. There was, however, no value for the C–H ... O hydrogen bond, and I could find very few papers where the possibility of the 'short' C ... O distance being such a bond was considered.

A few examples of 'short' C ... O contacts are given in Table 1. These occur mainly in the crystal structures of heterocyclic molecules but sometimes in those of compounds containing atoms of different electronegativity with, frequently, a conjugated double bond system or a series of double bonds. The carbon atom of the C–H group is directly attached to the hetero or the more electronegative atom or group, or is part of a conjugated double bond system containing a hetero atom. The right conditions exist for the activation of the C–H group and the formation of hydrogen bonds. It must now be shown that the

Table 1. Some 'Short' Intermolecular C ... O Distances

Compound	d(C ... O) in Å	Groups involved	Ref.
Caffeine	3.18	CH ... O (keto)	(3)
Theophylline	3.22	CH ... O (keto)	(4)
Glycyl-L-tyrosine hydrochloride	3.07	CH_2 ... O (water)	(5)

1,3,7,9-Tetramethyluric acid	3.00	CH_3 ... O (keto)	(7)
Acetyl choline bromide	3.00	CH_3 ... O (acetyl)	(8)
Caffeine	3.24	CH_3 ... O (keto)	(3)

Table 2 ANGLES CONNECTED WITH SOME OF THE 'SHORT' INTERMOLECULAR DISTANCES

Compound and hydrogen atom	*d*(H . O) in Å	∠C-H O	∠H-C O	∠H O C
Theophylline (H_1)	2 25	173 3°	4 7°	2 0°
Caffeine (H_1)	2 07	166 7	8 6	4 7
Ethylene carbonate (hydrogen positions calculated)	2 73	102 6	59 4	18 3
1,3,7,9-Tetramethyluric acid (H_1)	2 26	120 8	40 0	19 0
Caffeine (H_2)	2 76	109 1	53 9	17 1

hydrogen atoms are involved in the interactions if these are to be hydrogen bonds

In some of these compounds with 'short' intermolecular C . O distances the positions of the hydrogen atoms are known For these compounds all the relevant angles of the interaction have been calculated and a few examples and some of the angles are given in Table 2 For the CH group the value of *d*(H O), the distance between the hydrogen and oxygen atoms, is about 2 1 Å , which is less than 2 6 Å the sum of the van der Waals radii for these atoms The angles C–H O and H–C O are within the accepted limits for a hydrogen bond These interactions are therefore hydrogen bonds

In the case of the methylene and methyl groups, there is no tendency to form more than one 'short' contact This is in contrast to the NH_3^+ group, which can form three hydrogen bonds The angles for the CH_2 and CH_3 groups are very similar and, for all the examples considered, range from 22°–59° and 102°–142° for angles H–C O and C–H O respectively The hydrogen atom is no longer directed towards the oxygen atom as in the case of the CH group, but the hydrogen bond is not necessarily linear Steric hindrance from the other hydrogen atoms in these groups and the position assumed by the group which is forming only one 'short' contact may prevent a linear arrangement of this bond Until the limits in the angles representing the deviation from linearity of the hydrogen bond are known, it cannot be definitely stated whether these contacts formed by the methylene and methyl groups are true hydrogen bonds Nevertheless, it is felt that these interactions correspond to hydrogen bonds which are typical of these groups

There are many examples of 'short' intramolecular C . O contacts where activation of the C–H group occurs, for example, 2 87 Å in muscarine iodide[9], 3 01 Å in indirubine[10] These probably represent intramolecular C–H O hydrogen bonds

It is noteworthy that many of the compounds cited are molecules of biological importance The hydrogen bond is of great importance in the packing of this kind of molecule and it would seem that the C–H . O hydrogen bond may play a similar part, too

I thank Dr R Sparks for the use of his *Mercury* programme for calculating angles, and the University of London for the award of an Imperial Chemical Industries fellowship

MINERALOGY

The System Al_2O_3–B_2O_3

Numerous investigations have been made of the thermal behaviour of alumina–boric oxide mixtures In 1887 Mallard[1] identified a compound believed to be $3Al_2O_3$ B_2O_3 Later work by Baumann and Moore[2] and by Scholze[3] indicated the formula to be $9Al_2O_3$ · $2B_2O_3$. Scholze[3] reported an additional compound, $2Al_2O_3$ B_2O_3 A third boroaluminate has been recognized as the rare mineral jeremejevite, Al_2O_3 B_2O_3 (ref 4) Data on the stability of these compounds are conflicting, and no serious effort appears to have been made to incorporate them in a conventional phase diagram We present here a tentative phase diagram for the system Al_2O_3–B_2O_3, based on data from more than 100 runs carried out in the range 600°–1,650° C

Alumina–boric oxide mixtures were prepared from high-purity γ-alumina and crystalline boric oxide, or from the previously prepared boroaluminate compounds, $9Al_2O_3$ $2B_2O_3$ and $2Al_2O_3$ B_2O_3 Samples were sealed in platinum tubes to eliminate volatilization losses, and to ensure a water-free environment They were held for 16–24 hr , and occasionally up to 120 hr , in a platinum 60–rhodium 40 resistance furnace Temperatures were read with a platinum, platinum 90–rhodium 10 thermocouple frequently calibrated against the melting points of gold (1,063° C), diopside (1,391 5° C), and palladium (1,555° C) The fired charges were quenched in air or mercury, and phases were identified with the polarizing microscope and the X-ray diffractometer

Baumann and Moore[2] found $9Al_2O_3$ $2B_2O_3$ to melt incongruently at 1,950° C , whereas Scholze[3] set the melting point at 1,440° C In the present work no fusion was observed in a sealed-capsule sample of $9Al_2O_3$ $2B_2O_3$ held for 6 hr at 1,650° C The 1,950° C value is therefore selected as the more plausible Our tests indicate that $2Al_2O_3$ B_2O_3 melts incongruently to yield $9Al_2O_3$ $2B_2O_3$ and liquid at 1,035° C This is in essential agreement with the value of 1,050 ± 20° C given by Scholze[3] Attempts to synthesize jeremejevite at atmospheric pressure, and in a low-pressure hydrothermal bomb, proved unsuccessful Its reported synthesis by Michel-Levy[5] at about 4,000 atmospheres suggests that it may be a high-pressure phase The work of Golovastikov *et al* [6] indicates that jeremejevite may be a hydrated boroaluminate Our negative results in the attempted Al_2O_3 B_2O_3 synthesis are consistent with either of these two possibilities

Fig 1 incorporates the results of 135 runs on compound stability and liquidus curve determination Small crosses indicate the compositions and temperatures of the liquidus runs The liquidus curve is shown rising continuously from the melting point of B_2O_3 at 470° C The determined curve has been extended only to 1,545° C , when it has been extrapolated as a smooth dashed curve to the melting point of alumina at 2,020° C Conceivably, a two-liquid area might intervene in this extrapolated region However, B_2O_3 is known to behave towards other oxides in much the same way as does SiO_2 towards the same oxides Since SiO_2 shows no liquid immiscibility towards Al_2O_3, it is tentatively assumed that B_2O_3 also lacks an immiscible relation in the liquid region of the Al_2O_3–B_2O_3 system If a eutectic exists in this system it can scarcely differ appreciably, in composition or temperature, from the pure B_2O_3 end-member In fact, the proximity of the liquidus

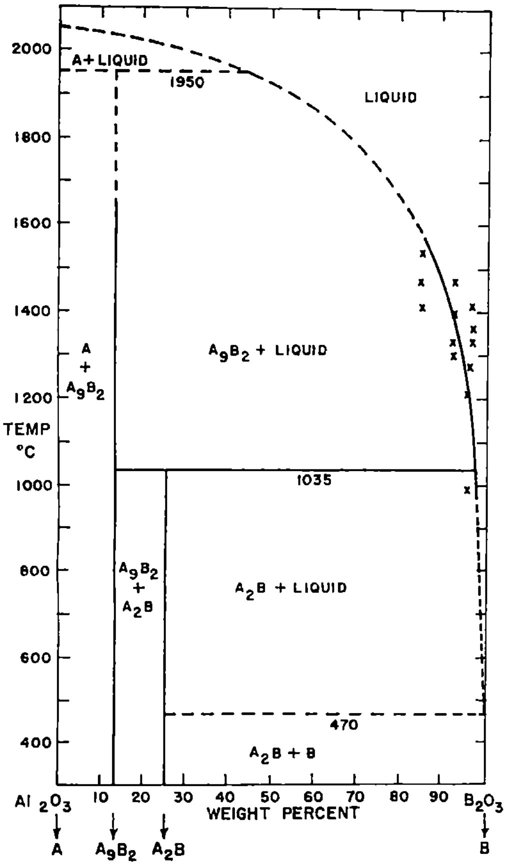

Fig 1

curve to the B_2O_3 extremity strongly favours the monotectic relation shown in Fig 1 Uncertainty as to the stability and composition of jeremejevite, and our own failure to synthesize it, has led to the omission of this phase from our diagram

Our extrapolated experimental liquidus curve indicates a much lower solubility of alumina in B_2O_3 than is suggested by pouring-temperature curve determined by Baumann and Moore[2] On the other hand, the solubility of alumina as determined by Foex[7] at 1,200° C is in good agreement with our liquidus Baumann and Moore[2] had also suggested a possible eutectic horizontal at about 200° C on the basis of the blistering of cones rich in B_2O_3 No evidence in support of such a relationship was encountered in this study

CHEMISTRY

Structure of Hydrides of Palladium

The recent determinations of activation energies for slow processes in palladium hydride[1,2] confirm new results obtained in this laboratory

The heat capacities of PdH_x recently completed for x = 0 5 and x = 0 75 are shown in Fig 1 along with points for other concentrations[3,4] Between 35° K and 85° K the heat capacity is obviously independent of the hydrogen concentration up to 0 75 H/Pd ratio

Warm drifts in the calorimeter were again noted Fig 2 presents a logarithmic plot of the warm drift versus the reciprocal temperature for the earlier and new data from the slope of which activation energies were obtained[3]

These results, summarized in Table 1, provide clues leading to a model consistent with modern ligand theory which leads directly to the observed zero point entropy of Pd_2H Neutron diffraction investigations place the hydrogen atoms in the octrahedral positions of the palladium lattice at room temperature[5] and down to 20° K (ref 6) In the proposed model applied to the β-phase, these hydrogens form sheets through hydrogen bonding with neighbouring palladium atoms in the lattice A square planar arrangement of hydrogens about the palladium atoms in these sheets is favoured by resonance leading to the W_{aa} term in the Lacher quasi-chemical treatment The sheets can take right angle bends in any direction, but never intersect[7]

Table 1 Activation Energies for Diffusion in PdH_x

Region of drift	x = 0 125	0 25	0 50	0 75
150° K –200° K	2 9 kcal	2 9 kcal	no drift	no drift
200° K –250° K	6 4 kcal	6 4 kcal	no drift	5 5 kcal

Simple numerology shows that at the composition Pd_2H all palladium atoms at the corners of the face-centred cubes are part of sheets, with hydrogen midway between each palladium atom in the sheets and with no hydrogens outside the sheets Above 0 50 H/Pd ratio cross planes of hydrogen and palladium sheets begin to form This explains the sudden change from metallic to non-metallic conduction around 0 50 H/Pd ratio noted by Schindler *et al* [8]

In the α-phase, hydrogen is randomly distributed between corner palladium atoms which are not part

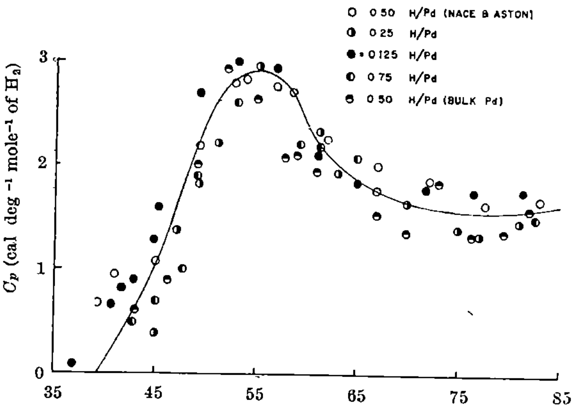

Fig 1 C_p of a mole of hydrogen in block palladium samples of ratio 0 75, 0 50, 0 25 and 0 125 H/Pd and palladium powder sample of 0 50 H/Pd ratio between 35° K and 85° K

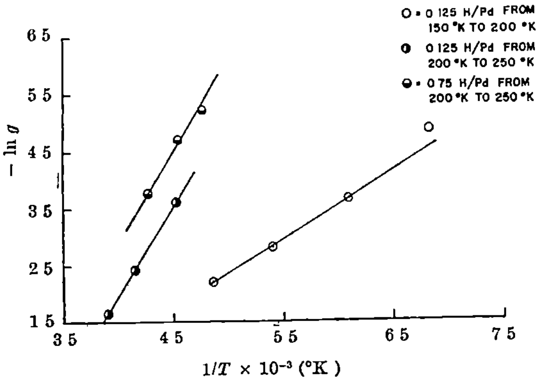

Fig. 2. Plot of reciprocal of T versus ln rate of heat evolution to give activation energies for the three samples

of sheets Thus at low temperatures, due to resonance stabilization of the β-phase, the α-phase has a negligible concentration of hydrogen, as follows from the calculations of Lacher Since resonance favours full occupation of the square planar positions, at low temperatures all vacancies in the sheets will be filled

Below the heat capacity peak at 55° K, PdH_4 molecules librate about an axis through the palladium atom and perpendicular to the fully occupied planes As the temperature increases this libration turns to hindered rotation (ring diffusion) and as rotation starts the potential barrier to rotation decreases (that is, the value of W_{aa} decreases) This is a co-operative type phenomenon and gives the type of heat capacities presented in Fig 1 Since the addition of more hydrogen to the sample merely forms larger sheets the heat capacity effect of the hydrogen is concentration independent

At temperatures where vacancies in the sheets exist, diffusion to neighbouring cells can occur through rotation (ring diffusion) Such a process, leading to filling of vacancies, is the cause of the warm drift starting at 150° K in the 0 125 H/Pd and 0 25 H/Pd compositions On rapid cooling, the system does not reach the equilibrium which favours less vacancies Its slow establishment produces the warm drifts near 150° K with activation energy of 2,900 calories per mole At 0 50 H/Pd ratio and above the sheets of the β-phase are filled and there can be no lack of equilibrium with respect to the filling process By nuclear magnetic resonance methods, valid at equilibrium, Spalthoff[1] measured the activation energy of this neighbouring cell diffusion in a 0 64 H/Pd ratio sample at equilibrium conditions and found an activation energy of 2,400 ± 300 calories

The warm drifts at 200° K and higher are due to long-range diffusion from α- to β-phase or from one sheet to another By rapid cooling the sample cannot establish the true equilibrium which requires less hydrogen in the α-phase The slow return to equilibrium requires the long-range diffusion occurring above 200° K with an activation energy near 6,000 calories The 0 50 H/Pd ratio has no incomplete sheets (no β-phase vacancies) and therefore could not exhibit a warm drift in this region Above 0 50 H/Pd ratio the sheets are cross-linked to form a set of systems of sheets at right angles with no vacancies in any single system Only with the resonance energy thus available can the extra repulsion be overcome

The activation energy for long-range diffusion is the same as the measured activation energy (6–8 kcal) for diffusion of hydrogen through palladium[9], as it should be Rapid cooling produces lack of equilibrium with respect to the size of these units which is slowly restored by the long-range diffusion

At the composition 0 50 H/Pd if certain hydrogens on palladium atoms rotate through $\pi/2$ the sheets suffer a sharp bend by $\pi/2$ Since this rotation can occur at random at equilibrium the situation is equivalent numeralogically to that of ice There are three non-participating face-centred palladium atoms to each corner one Since the species analogous to water is PdH_2 in each corner palladium atom, the basic unit is Pd_4H_2 In keeping with this it was found[10] that the zero point entropy of two Pd_2H units in palladium black is 1 18 ± 0 36 (2 × 0 59 ± 0 18) The theoretical value is 0 82

Action of Manganese Dioxide on D-Fructose

Many organic compounds can be selectively oxidized by manganese dioxide at room temperature in non-aqueous media[1,2] High oxidative yields from both primary and secondary αβ-unsaturated alcohols[3] and saturated alcohols[4] have been reported under suitable experimental conditions Little work has been reported on the action of manganese dioxide on carbohydrates Mannitol in aqueous solution has been shown to undergo decarboxylation[5], while recently Bose, Foster, Salim, Stacey and Webber[6] isolated several products from disaccharides treated at 100° for 1 hr with manganese dioxide

The present communication describes the interaction of D-fructose with manganese dioxide at room temperature Since the reaction is heterogeneous, finely ground oxide was used throughout and afterwards all solutions were centrifuged before examination In a typical experiment, D-fructose (1 5 gm) in distilled water (150 ml) was shaken with manganese dioxide (7 5 gm) for 16 5 hr , when $[\alpha]_D$ rose from − 92 5 to − 16 9 No carbon dioxide was evolved during this period The solution was chromatographed in butan-1-ol/acetic acid/water (4 1 5), and spraying with ammoniacal silver nitrate revealed seven spots, together with some streaking, R_F 0 03, 0 09, 0 14, 0 18, 0 23, 0 27 and 0 46 (faint) Potassium permanganate (0 1 N) was decolorized on treatment in the cold, accompanied by precipitation of manganese dioxide The solution gave a positive Schiff reaction

The solution (50 ml) was heated with o-phenylene diamine at 60° for 10 min On cooling the yellow crystals which separated (about 20 mgm) were crystallized from hot water to give 2-(arabino-tetrahydroxybutyl) quinoxaline (I), m p 192°, λ_{max} 237 mμ and 319 mμ (ref 7) Addition of 2 4-dinitrophenylhydrazine solution in 2 *N* hydrochloric acid (200 ml) to a further portion of the solution (80 ml) gave a yellow precipitate in less than 5 min at room temperature Recrystallization from ethanol gave glucose-2 4-dinitrophenylosazone, m p 258° (II) Fructose under similar conditions did not afford these derivatives

Generally, considerable excess of manganese dioxide to substrate (5 to 20 1) is required[2] although Stacey *et al* [6] used equal weights of oxide and disaccharide Optical rotational measurements (Fig 1) indicate that manganese dioxide in excess promotes greater reaction This may be expected owing to the heterogeneous nature of the reaction Exact reproduction in chemical change has not been achieved, possibly due to variation in oxide particle size from one run to another

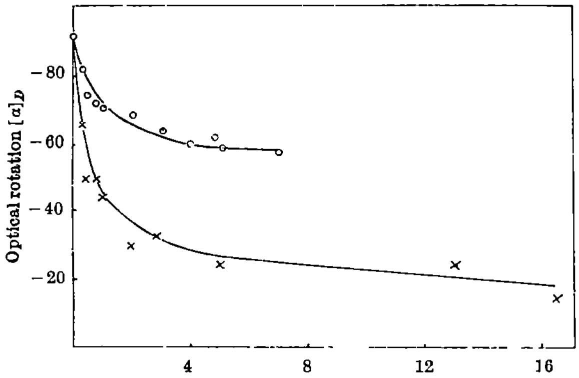

Fig 1 Change in optical rotation of aqueous D-fructose solutions on shaking with manganese dioxide ○, MnO_2/D-fructose, 1 1 (by weight), ×, MnO_2/D-fructose, 5 1 (by weight) 2 dm tube Initial $[\alpha]_D = -92$ 5

None of the solutions showed characteristic absorption spectra between 210 and 400 mμ, indicating the absence of keto or enediol groupings

In another experiment, the residual manganese dioxide from the above 16 5-hr run was resuspended in distilled water (50 ml), centrifuged and dried at 250° The supernatant liquid had zero optical rotation, but gave a positive Schiff test It is therefore possible that some degraded material remained adsorbed on the oxide Fresh fructose solutions could be degraded in similar fashion with this dried manganese dioxide

Manganese dioxide is an efficient, and in some cases selective, reagent for the conversion of primary alcohol groups to aldehydes[4] Such a reaction with the —CH_2OH group at C_1 in D-fructose would lead to 2-oxo-D-arabino-aldohexose The isolation of compounds I and II together with a spot, R_F 0 18, support this view However, chromatographic analysis of even 1, 2 and 3 hr runs indicates that at no time is the mechanism selective The Schiff colour developed immediately with these solutions exhibited a peak at 550 mμ which provided additional evidence for the presence of osone material[8]

Throughout, Hopkin and Williams type manganese dioxide was used (about 90 per cent manganese dioxide together with other oxides of manganese only) Similar patterns, but overall less degradation, were effected using manganese dioxide prepared by pyrolysis of manganese carbonate at 250° (ref 4)

Sorption of Dissolved Phosphorus from Sea-water by means of Aluminium Hydroxide

EXPERIMENTS have been conducted in this laboratory on the sorption of dissolved organic matter from sea-water on *in situ* precipitates of ferric and aluminium hydroxides Particular attention was paid to the sorption of dissolved organic phosphorus compounds with the view of facilitating the preservation of total phosphate samples collected on oceanographic cruises It was found that all the dissolved phosphorus in sea-water (both inorganic orthophosphate and organically combined phosphorus) can be removed from solution on a combined precipitate of aluminium and magnesium hydroxides The following procedure is recommended

To 50 ml of sea-water filtered through a 'Millipore *HA*' membrane and dispensed into a centrifuge tube, add 1 ml of 0 3 *N* sodium bicarbonate solution and 0 5 ml of a saturated solution of potassium aluminium sulphate Mix thoroughly and leave for at least 4 hr , then centrifuge in a swing-out head at 300*g* for 5 min Add a further 0 5 ml of potassium aluminium sulphate solution and mix by gentle swirling of the tube, leaving the first precipitate undisturbed After another 4 hr , centrifuge as before Add two drops of 4 *N* ammonium hydroxide to precipitate magnesium hydroxide, mix by swirling, and stand for 2 hr Finally, centrifuge at 600*g* for 5 min , pour off the supernatant, and dry the mouth of the tube with filter paper The precipitate contains all the dissolved phosphorus of the original sample

The total phosphorus content of the precipitate may be estimated by the procedure of Burton and Riley[1] Since there is little or no chloride remaining, it is sufficient to use only 0 4 ml of 70 per cent perchloric acid and 0 2 ml of nitric acid (s g 1 42)

One example of the efficacy of the method is given in Table 1, which shows the recovery of total phos-

Table 1 TOTAL PHOSPHORUS CONTENT OF ALGAL FILTRATE (μGM. PO_4—P/l)

phorus by the sorption procedure from a filtrate of a mixed marine algal culture. The filtrate was used as an experimental medium in order to test the method at higher phosphorus-levels than were normally encountered in the natural sea-water samples used for the development of the method (10–30 μgm phosphorus/litre). The algal culture was filtered through a 'Millipore *HA*' membrane, and sub-samples of the filtrate taken either for direct digestion by the procedure of Burton and Riley[1] or for treatment by the recommended sorption technique with subsequent digestion of the precipitate. The inorganic orthophosphate content of the filtrate was estimated by a routine acid molybdate–stannous chloride technique[2] and found to be 26 μgm phosphate-phosphorus/l. Therefore more than half the phosphorus in the filtrate was organic.

The technique has the advantage that considerable concentration of low-phosphate water can be obtained, since the precipitate will dissolve in as little as 5 ml of dilute acid. Digestion is simple and rapid, for volumes to be evaporated are small and there is no decrepitation. Reagent blanks are low and there is no 'salt error'. The technique might also be useful for the preliminary isolation of organic phosphorus compounds in sea-water prior to further examination.

Recovery of phosphorus is low and erratic when the precipitation is carried out in wide or shallow vessels, when the precipitate is recovered by filtration or when the precipitate is agitated while in contact with the supernatant. Similarly, some phosphorus remains in the supernatant if the sample is centrifuged too soon. A minimum of 4 hr standing is required for the transition from the initially formed unstable colloidal solution of aluminium oxyhydroxide through the α-hydroxide to the insoluble but stable γ hydroxide. Time of standing is not critical after this initial 4-hr period.

BIOPHYSICS

Protein in the Nucleus Pulposus of the Intervertebral Disk

The nucleus pulposus of the normal human intervertebral disk consists of collagen fibrils dispersed in a gel of polysaccharide and protein complexes. During ageing collagen fibrils are deposited as a matrix showing increasing orientation with age as seen from X-ray diffraction investigations[1]. In the case of specimens of more than 70 years of age, the normal photograph shows with the diagram of oriented collagen a clearly defined ring of spacing 4.7 Å, which is similar to that associated with a denatured β-protein[1]. The presence of other components in the disk, for example, calcium phosphate, etc., will be discussed in a later publication. It was postulated from consideration of earlier work[1] that the soluble protein molecules normally found in a folded form in the nucleus had unfolded and formed a hydrogen-bonded lattice which gave rise to this spacing.

From this it was thought possible that in certain cases the typical denatured β-protein ring might be found in younger specimens, in consequence an extensive survey was made of disks from all age groups. The results of this survey were based entirely on X-ray diffraction observations (using copper K_α radiation at 40 kVp and 40 m.amp.). The specimens were freeze-dried and exposures were of only 0.5 hr duration in order that the swollen matrix could be preserved. About four samples from each nucleus were examined. The results are summarized in Table 1.

Table 1

Age range (years)	Without β-protein reflexion	With β-protein reflexion	Percentage with β-protein
0–15	15	0	0
16–30	13	3	19
31–45	8	1	11
46–60	2	5	71
61–75	11	15	58
76 and over	0	4	100

Ten per cent below 45 years of age showed the β-protein reflexion, while 65 per cent above 45 years of age showed the β-protein reflexion. About 20 per cent between 16 and 45 years showed the β-protein reflexion, this is of some significance since the age range 0–15 years included a large number of very young disks (less than 3 weeks old). In general the reflexion when it appears in the photograph of the younger disks is weaker and more diffuse, but in aged specimens is sharp and strong. There is a high coefficient of correlation 0.92 between the appearance of the 4.7 Å reflexion and the age of the disk, which suggests that the occurrence of the β-protein ring may be taken as an indication of what has been referred to by other writers[2] as "pathological ageing".

Further preliminary investigations[3] indicate that the incidence of the β-protein reflexion in the nuclei pulposi of prolapsed disks is higher than in normal disks. If further investigations, which are being carried out, confirm this then the prolapsed disks can be regarded as having undergone some form of "pathological ageing". It might be possible, therefore, that the younger disks of Table 1 showing the β-protein ring would have been more susceptible to prolapse than those which did not. On the other hand, the presence of the β-protein phase may be consistent with a greater degree of fibrosis in the nucleus, and if this were so then the disk may be less susceptible to prolapse than one with a lower degree of fibrosis. If, however, some of the increased β-content of the nucleus is associated with the process of prolapse and is not solely inherent in the nucleus before this occurs then it could be that the physical disturbance caused by prolapse may initiate a spontaneous transformation of some of the soluble nuclear protein to an insoluble β-form, a condition somewhat similar to that obtaining in the transformation of soluble to insoluble protein in denaturation (for example soluble → insoluble silk fibroin).

Measurement of Creep in Keratin Fibres

CREEP characteristics of wool fibres in water have yielded valuable information on the fine structure of keratin[1–4] Creep fluidity at high extensions is also of technological significance[5]

The absence of plastic flow in unmodified fibres (as made evident by the perfect reversibility of extensions greater than 70 per cent) and knowledge of the α–β transformation has led to the use of constant loads throughout creep tests on the assumption that the load per molecular chain remains constant Even under these conditions variations among fibres drawn from the same staple are large with respect to initial extension and rate of creep[6]

We have noted that the occurrence of the well-known stages of the load-extension curve are relatively constant with respect to extension but extremely variable with respect to stress Stress at 30 per cent extension varies between 4 and 7 kgm /mm², two typical examples are set out in Table 1

Table 1 STRESS OF WOOL FIBRFS AT 30 PER CENT EXTENSION (*S*30)

Sample *A* Fibre No	Sample *A* Diameter (μ)	Sample *A* *S* 30	Sample *B* Fibre No	Sample *B* Diameter (μ)	Sample *B* *S* 30
1	22 4	4 60	1	18 2	6 13
2	24 7	4 62	2	21 4	5 56
3	26 0	4 51	3	23 8	5 78
4	21 8	4 75	4	21 0	5 98
5	19 2	5 88	5	20 2	6 31
6	20 3	4 65	6	21 4	6 06
7	22 4	5 36	7	20 1	6 44
8	21 3	4 69	8	19 2	6 02

The application of a constant stress of 6 kgm / mm² would result in an initial extension of 30–50 per cent for sample *A* fibres, whereas sample *B* fibres would give initial extensions of *c* 30 per cent A comparison of these two samples would not involve creep at the same level of extension

It is well known that extension to 30 per cent under specified conditions does not damage wool fibres[7] and by calibrating a fibre in this way it is possible to estimate, with reasonable accuracy, the load required to give any extension Details of an experiment comparing this technique with the constant stress method are given in Table 2

Table 2

Group	Fibre No	*S* 30 kgm mm²	Stress applied kgm mm²	Stress applied as a percentage of *S* 30
1	1	5 54	3 88	70
	2	5 75	4 03	70
	3	6 14	4 30	70
	4	5 57	3 90	70
			mean 4 03	
2	5	5 01	4 03	80 4
	6	5 47	4 03	73 7
	7	5 77	4 03	69 8
	8	4 68	4 03	86 1
			mean 4 03	

Both groups (drawn from the same staple) have the same mean stress applied Group 1 fibres have variable stresses but each stress represents a constant fraction of *S*30, whereas Group 2 fibres have constant stresses bearing no relation to *S*30 The creep curves of these fibres in distilled water at 15 4° C is illustrated in Fig 1

The great reduction in variation of fibres in Group 1 indicates the value of the technique in experiments requiring the comparison of creep properties at a definite extension We have used the method with equal success in the post-yield region for example, by using stresses of 130 per cent *S*30 It appears that investigations of load-extension of fibres to the breaking point will enable accurate prediction of creep properties at any given load in unmodified keratin fibres

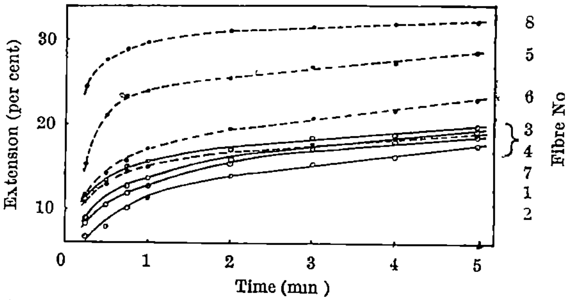

Fig 1 Creep of wool fibres in distilled water at 15 4° C Full lines, fibres under stress equal to 70 per cent *S* 30, broken line, fibres under mean stress of 4 03 kgm /mm.²

BIOCHEMISTRY

Identification of Sugars in Royal Jelly

THE presence of sugars in the nutrients of the honey-bee termed royal jelly has been reported, but the analyses were based on fermentation and reducing power investigations[1,2] or paper chromatography evidence[3,4] The chromatographic evidence indicated the presence of components having the same R_F values as glucose and sucrose in all samples studied, and in certain samples, R_F values corresponding to sucrose, maltose and ribose Because this evidence was not based on an evaluation of physical constants of the crystalline sugars and their derivatives, an investigation was undertaken to isolate and identify precisely the carbohydrate components of this bee larval food

A fresh quantity of royal jelly (100 gm) (kindly supplied by R B Wilson, Inc , 250 Park Avenue, New York, 17) was placed in casing and dialysed in water at 5° C with frequent changing of this solvent, until the dialysate showed a negative Molisch test This required 20 days and about 5 litres of water The dialysate was concentrated (*in vacuo*) at 40° C to a thin syrup and the residual water removed by adding increments of dry ethanol and evaporating the ethanol–water azeotrope under vacuum As the water was removed, the syrup hardened into a plastic solid which, after complete dehydration, was then transferred with 100 ml of ethanol to a Waring blender During the homogenization process which followed, requiring 15 days, a total of 5 litres of dry ethanol, added in 150 ml increments, was used for extracting the sugars from the amorphous product Approximately 15 per cent of the dialytic substance was insoluble in ethanol and may be principally the pteridin compound which has been reported[5]

The alcohol-soluble components, principally sugars, were concentrated (*in vacuo*) at 40° C to a thin syrup and the sugar constituents separated using the method of descending paper partition chromatography[6]. A sample of the syrup (approximately 50 µl.) was placed on the 'starting line' of Whatman No. 3 *MM* chromatography paper (18.25 in. × 22.5 in.) and the sugar components subjected to partition during 33 hr. of irrigation, by the solvent, pyridine/ethyl acetate/water (4:10:3). The paper was dried, and three small strips (1 cm wide) were cut lengthwise from the middle and edges of the paper and sprayed with Tollen's reagent. After heating the strips to hasten the development of 'spots' denoting the exact positions of the separated sugars, the three strips were replaced alongside the rest of the chromatogram and the 'spots' used as indices to deduce the location of the sugars remaining on the unsprayed, main portion of the paper. The sections of paper containing a sugar were cut from the chromatogram and each placed in beakers with water (20 ml.) to elute the sugars from the paper. Nineteen additional fractionations using chromatography paper were effected in this manner.

After combining the related sugar fractions from the twenty chromatograms, the solutions were filtered through glass wool and concentrated (*in vacuo*) to a thin syrup. Three pure sugar solutions were thus obtained from royal jelly and crystalline products were isolated by crystallization (twice) from aqueous methanol (50 per cent v/v).

The sugar corresponding to D-glucose showed a m.p. of 146°–149° C. $[\alpha]_D^{23} = +51.7°$ in water, and an R_F value of 0.509 (in the solvent quoted). An authentic sample of D-glucose showed a m.p. of 147°–149° C., $[\alpha]_D^{23} = +52°$ in water, and an R_F value of 0.509 in the same solvent. The sugar corresponding to D-fructose showed a m.p. of 108°–109° C., $[\alpha]_D^{23} = -86.4°$ in water and an R_F value of 0.547. An authentic sample of D-fructose showed a m.p. of 108°–109° C., $[\alpha]_D^{23} = -92.0°$ in water and an R_F value of 0.546. The sugar corresponding to D-sucrose showed a m.p. of 185°–187° C., $[\alpha]_D^{23} = +65.5°$ in water and an R_F value of 0.358. An authentic sample of D-sucrose showed a m.p. of 186°–187° C., $[\alpha]^{23} = +66.5°$ in water, and a R_F value of 0.358.

To confirm the identity of these sugars the acetate derivatives were prepared following a procedure as described in a recent paper[7], except for a modification of the size of apparatus and proportions of reagents used. Table 1 lists the quantities of reactants used in the present work, the melting points of the acetate derivatives which were isolated, and the melting points of the corresponding reference acetate compounds. The size of apparatus and amounts of wash solutions, etc., used were modified so as to accord with the amounts of reagents used.

Considering the results of these experiments, especially the close agreement between the melting points of the experimental and reference compounds, it is to be concluded that D-glucose, D-fructose, and D-sucrose are components of fresh honey-bee royal jelly. It seems likely that these three sugars in royal jelly are derived from plant nectars, where they are also present as the principal sugars[8], and present in relatively high concentration.

Table 1. TABLE OF VALUES REGARDING THE ACETYLATION OF SUGARS

Reactants	Acetylation of D-Glucose	D-Fructose	D-Sucrose
Weight of sugar (gm.)	0.0178	0.0395	0.0187
Weight of catalyst (gm.)	0.002	0.002	0.002
Volume of acetic anhydride (ml.)	2.00	2.00	3.00
Products			
Melting point of derivative (° C.)	96–97	128–129	72–73
Melting point of derivative lit. value (° C.) (ref. 7)	97	128–129	73.5

It was observed that trace amounts of other substances, possibly sugars, provided 'spots' with Tollen's reagent on developed chromatograms. Although maltose[3] and ribose[4] have been reported to be components of royal jelly, we did not find conclusive evidence of these sugars in the samples with which we worked.

It is to be noted that the royal jelly used for this experiment was obtained from a commercial source and therefore is assumed to be a representative, but only 'average', sample. There may be qualitative and quantitative differences in the carbohydrate components when comparing specific types of larval food, this was found to be the case for lipid components of royal jelly[3].

The quantitative analysis of glucose, fructose, and sucrose in royal jelly has been concluded and soon will be submitted for publication.

I thank Mr. R. Swor for his assistance in carrying out part of this work. This investigation was supported in part by grant *RG*-7233 of the U.S. Public Health Service.

Biosynthesis of Royal Jelly Acid from Sucrose

THE relatively large amounts of royal jelly acid (10-hydroxydec-2-enoic), about 8–9 per cent in lyophilized royal jelly, invites speculation as to its biosynthesis. Recently, Law and Weaver[1] reported on experiments using isotopically labelled compounds in an effort to demonstrate formation of hydroxy fatty acids in worker bees. Sodium acetate-1-^{14}C and sodium stearate-1-^{14}C were fed to worker bees and also included in an incubation medium with excised mandibular glands. In both cases considerable radioactivity was detected in lipid extracts of the mandibular glands, but the hydroxy acid fraction did not become labelled.

We now report on our experiments involving the feeding of uniformly labelled sucrose. About 1.5 lb. of worker honey bees were deprived of their queen, confined on two frames of honey and pollen and forced to rear queen cells. Sucrose, uniformly labelled with carbon-14 was fed to the bees immediately on confinement. In the first test 10 µc. of sucrose labelled with carbon-14 was diluted in 70 ml. of 1:1 sucrose water syrup and placed in two feeder bottles. The solution was consumed in about 5 hr. In the second and third tests the dosage of labelled sucrose was doubled and fed in the same way.

Five hours after confinement thirteen grafted queen cells were given to the confined bees. Royal jelly was collected at the end of 1, 2 or 3 days and the cells immediately re-grafted and returned to the bees Each group of bees was used for 6–7 days after which time the confined bees became distressed to the point that no further queen rearing was possible Two collections of jelly at 3-day intervals were found to give an optimum yield Radioactivity in the jelly did not decrease up to 7 days after feeding A total of 8 8 gm (fresh weight) of labelled royal jelly was produced

A sample of each collection of royal jelly was dried and checked for radioactivity on a Nuclear-Chicago model *D*47 gas-flow detector The acids from the royal jelly were isolated and separated chromatographically by the method of Brown and Freure[2]. The chromatograms were checked for radioactivity Only the spot corresponding to 10-hydroxydec-2-enoic acid (R_F 0 70) was found to be active The spot was eluted and a total of 80 mgm of radioactive royal jelly acid was recovered from 6 gm of whole royal jelly The recovered acid was shown to be identical with an authentic sample of inactive royal jelly acid by comparison of infra-red absorption spectra

Variations in the Blood Saccharoid Fraction in Diabetes

Recent reports have stressed the advantages of using highly specific 'glucose oxidase' methods for the clinical determinations of blood sugars[1–3] Traditional methods, such as those of Folin and Wu measure the total reducing capacity of the blood, and include the so-called saccharoid fraction as well as the true glucose-level The exact nature of this fraction and its significance in pathological conditions, is not yet fully understood

Clinical investigations have suggested that in a variety of conditions affecting blood sugar there is little correlation between blood glucose and the saccharoid fraction, and that this latter fraction is erratic and unpredictable during glucose tolerance tests Saifer and Gerstenfeld[1] believe that this fraction is significantly increased in diabetic patients, and Marks[2] has shown a reduction in the saccharoid fraction following insulin therapy, although the fall is delayed and erratic compared with that of the true glucose fraction Similar clinical studies are being carried out in this department, together with corresponding determinations on normal, alloxan-diabetic and insulin-treated alloxan-diabetic rats Preliminary results of this latter investigation are shown in Table 1 and Fig 1 Diabetic rats had been treated 3–4 months previously with 180 mgm alloxan per kgm body-weight (2 per cent solution, citrate-phosphate buffer, *p*H 4) and had blood sugars greater than 200 mgm per cent (glucose oxidase). Table 1 shows that the true glucose-level increases from a mean of 79 ± 2 61 to a mean of 253 ± 17 8 This represents an increase of 3 2 times. The saccharoid fraction (obtained by subtraction) shows a parallel increase, although the factor is somewhat larger (4 0 times) When diabetic rats are treated with insulin (100 units/kgm) this trend is reversed as shown in Fig 1 It would appear that in the case of the alloxan-diabetic and insulin-treated rat, corresponding changes occur in both the true glucose fraction and the saccharoid fraction It is of interest that in the rat approximately half the value obtained by the Folin–Wu method of estimation is due to substances other than glucose This is higher than the corresponding fraction in the human, where they represent approximately 25 per cent of the Folin–Wu value It appears that there may be a marked and characteristic species difference and it is interesting that Hernandez and Coulson found no evidence of a saccharoid fraction in the alligator[4]

Table 1 Blood Glucose-Levels of Normal and Diabetic Rats measured by Folin–Wu and Glucose Oxidase Methods
The values are the mean of 9 normal and 6 diabetic animals

	Folin–Wu (mgm per cent)	Glucose oxidase (mgm per cent)	Saccharoid fraction (by difference)
Normal rat	136 9 ± 4 7	79 4 ± 2 6	57 4 ± 3 8
Diabetic rat	484 0 ± 48	253 3 ± 17	233 0 ± 30

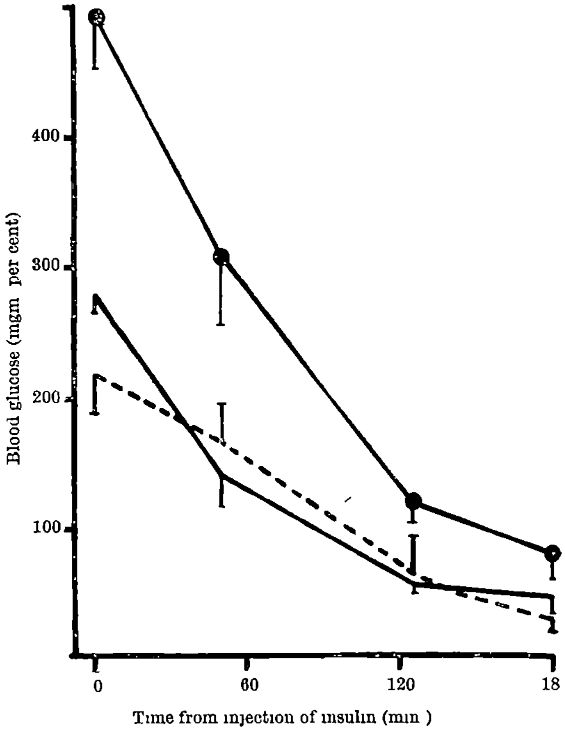

Fig 1 Glucose-levels in blood of alloxan-diabetic rats following the injection of insulin Each point represents the mean of three animals The vertical lines indicate the *S E* ●—●, Folin–Wu, —, glucose oxidase, – – –, 'saccharoid fraction' (difference)

These results emphasize the importance of standardizing methods of glucose estimation, not only clinically but also in experimental animal investigations

Crystalline Œstrone isolated from Urine of the Laying Hen

Although œstriol, œstrone and œstradiol have been detected in mixed avian excreta[1] and in extracts of ovaries of laying hens[2] by chromatographic methods, it would appear that only œstradiol-17β has been isolated hitherto from avian material in crystalline form and identified by infra-red spectrophotometry[3]. We have now secured similar evidence for the presence of œstrone in avian urine.

Approximately 30 l. urine (equivalent to 128 bird-days) was obtained from a laying hen furnished with exteriorized urethral orifices by the method of Dixon and Wilkinson[4]. Œstrogen extracts of the acid-hydrolysed urine were prepared by the method of Bauld and Greenway[5], and the lipophilic fraction was chromatographed on paper in a chloroform–formamide system[6]. The presumptive œstrone zones were cut out and eluted with methanol/dichloromethane (1 : 1 v/v). The solvent was removed and the residue dissolved in a mixture of benzene and carbon tetrachloride (1 : 2 by vol.) and purified by passage through a column of Woelm alumina as described by Ittrich[7]. After removal of the solvent the residue was crystallized twice from aqueous ethanol. The final yield was approximately 0·25 mgm.

The sample was dissolved in acetone and the solution evaporated on powdered potassium bromide, which was then ground by hand and pressed into a disk. A sample of reference œstrone (Steroid Laboratories, Montreal) was similarly prepared. Spectrophotometry was performed with a Perkin–Elmer model 21 spectrophotometer fitted with a sodium chloride prism.

The infra-red absorption spectra of the presumptive œstrone from hen's urine and of the reference œstrone are shown in Fig. 1. There were differences in the region of —OH stretching bands, but these were probably a consequence of differences in crystallinity or water absorptivity as between the samples. There was excellent agreement between the two spectra for all points below 2,000 cm.$^{-1}$. Accordingly it can be concluded that the crystalline material isolated from hen's urine was identical with the reference œstrone.

This work was supported by a grant-in-aid of research (No. *BT*-56) from the National Research Council of Canada.

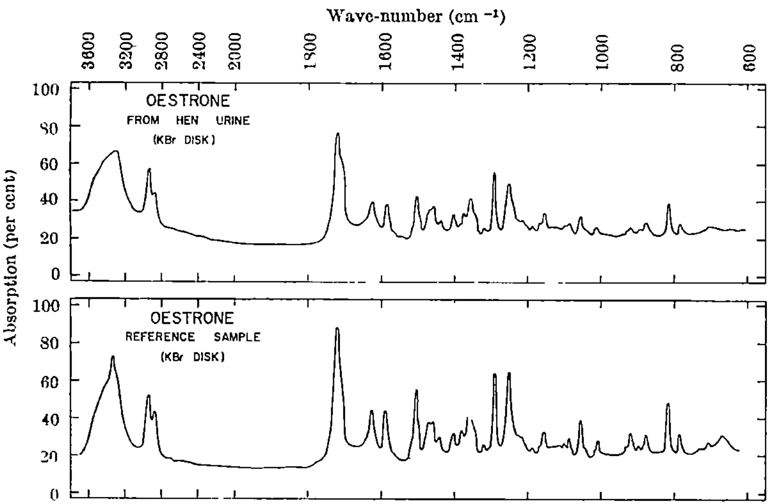

Fig. 1. Upper curve: Infra-red absorption spectrum of crystalline œstrone isolated from urine of laying hen. Lower curve: Infra-red absorption spectrum of reference œstrone

We thank Dr. R. Norman Jones and Mr. R. Lauzon, National Research Council of Canada, Ottawa, for determining the infra-red absorption spectra on which the identification of the crystalline œstrone from hen's urine was based.

Effects of Administration of Oxytocin and Prolactin on Nucleic Acids and Phosphoprotein Contents of Mammary Glands in Lactating Rats

Benson and Folley[1] have demonstrated from the histological point of view that the injection of oxytocin as well as prolactin into lactating rats after removal of their litters showed a marked retarding effect on the involution of mammary gland tissue, and this finding was confirmed by us[2] and others[3,4]. In previous experiments[2,5], however, we failed to see the effects on the *in vitro* respiratory activity of the mammary gland tissue.

Contents of deoxyribonucleic acid (DNA) of the mammary gland under various conditions have been estimated by many workers[6–9], and are considered as an indicator of the quantity of parenchymal tissue in the gland. Amounts of ribonucleic acid (RNA) and RNA : DNA ratio in the lactating mammary gland appear to be closely related to the rate of milk-protein synthesis taking place in the gland. In addition to these, amounts of phosphoprotein contained in the gland can be regarded as a conventional scale of milk accumulation in the gland[9], since phosphoprotein found in the gland is mainly derived from casein.

It was considered of interest, therefore, to reinvestigate the problem by using the determinations of nucleic acids and phosphoprotein in the gland.

Thirty-nine Wistar strain female rats in first lactation, weighing 170–220 gm., were used. Litters were reduced to six on the first day of lactation, three of each sex being kept whenever possible. They were weaned at the stage of full lactation (on eleventh–thirteenth day of lactation). Hormonal treatment was started from the afternoon of the weaning day and continued for 3 days. Oxytocin ('Syntocinon', Sandoz, Ltd., Basle, 1·0 and 2·0 i.u. in 0·5 ml. of

‡ The values are significantly different from those of the weaning control group ($P < 0\ 01$)

§ The values are significantly different from those of the weaning control group ($0\ 01 < P < 0\ 05$)

distilled water) was injected intraperitoneally three times daily and prolactin ('Luteotrophin', Squibb and Sons, Ltd , New York, 5, 25 and 50 I U in 0 5 ml of distilled water) was injected intramuscularly twice daily Seven rats, injected with 0 5 ml of distilled water intraperitoneally three times daily for 3 days after the weaning and six rats on the fifteenth day of lactation, were served as the weaning and the normal lactating controls respectively 30–60 min after the last injection, rats were killed by decapitation Six posterior mammary glands were quickly removed from the skin and stored in deep-freeze after weighing

DNA, RNA and phosphoprotein in the mammary gland were extracted and fractionated according to the method of Schneider–Schmidt–Thannhauser[10] with the Delory's treatment[11] Perchloric acid was used as a protein-precipitating and nucleic acid-extracting agent instead of trichloroacetic acid Nakamura's modification[12] of Allen's method[13] was used in the determination of phosphorus contents of nucleic acids and phosphoprotein The results obtained were expressed as DNA–P, RNA–P and phosphoprotein–P respectively in terms of mgm per total posterior mammary gland which was checked by body-weight of the animals (Table 1)

Administration of prolactin effectively retarded the involution of the mammary gland which was caused by the removal of litters in lactating rats Considerably large amounts of DNA–P and RNA–P remained in the glands of rats treated with prolactin even at the dosage-level as low as 10 I U a day, while only small amounts of them were found in the glands of rats which received only water In the largest dose group (100 I U /day of prolactin), structural integrity of the glands which was expressed by the DNA–P contents seemed to keep the level of normal lactation Well-maintained DNA–P contents of the glands in the prolactin-injected group agreed well with the observations of previous workers obtained from the histological point of view[1,2,14–16]

Maintaining the high DNA–P/RNA–P ratio and the relatively large amounts of phosphoprotein by the administration of prolactin seems to suggest that protein synthesis is still continued in the mammary gland under experimental conditions It is of interest to compare these results with those of previous experiments showing the immediate cessation of fat synthesis after the removal of litters despite the same hormonal treatment, although an essential difference between the biochemical significance of the RNA/DNA ratio and that of the respiratory-quotient value as an indicator of synthetic activity of the mammary gland should be taken into consideration It may be suspected that fat synthesis in the mammary gland is damaged more than the protein synthesis in the same gland by the ill-effect of engorgement

Daily administration of oxytocin retarded the depression of DNA–P content significantly, but the RNA–P/DNA–P ratio of oxytocin-treated groups was almost equal to or lower than that of weaning control group

It can be deduced from these results that the effect of oxytocin on the involution of mammary glands is not similar to that of prolactin Oxytocin administered to the lactating rats after the removal of litters affects only the structural integrity of the gland tissue, while prolactin administered in the same way, at least in the doses used, maintains both structural integrity and metabolic activity of the tissue

Amounts of PP–P found in the mammary gland of oxytocin-treated groups were less than those of any other experimental groups These results seem to indicate the accelerated re-absorption of accumulated milk[17–19] which is expelled from the mammary alveoli into the mammary ducts by the milk-ejecting action of oxytocin

We thank Dr R B Edwards (Squibb and Sons, Ltd , New York) for a supply of prolactin preparation ('Luteotrophin', Squibb) and Drs R W Zwicky and H Ogura (Sandoz, Ltd , Tokyo) for oxytocin preparation ('Syntocinon', Sandoz) This work was supported in part by a grant-in-aid for Scientific Research from the Ministry of Education, Japan

Developmental Changes in the Plasma Protein Pattern of the Mouse

Knowledge of the changes in the pattern of plasma proteins during the development of the mouse is desirable not only from the embryological but also from the genetical point of view, because of the existence of many inbred lines of this versatile laboratory animal.

Smithies's technique of starch-gel electrophoresis[1] with Poulik's discontinuous buffer system[2] was applied to blood plasma from strain *A* mice. Each sample was carried by a small strip of filter paper inserted in a slit in the starch-gel. This procedure apparently immobilizes the γ-globulins[1], so that the observations that follow do not concern this fraction.

Plasma from adult females at various stages of pregnancy gave twelve fractions in the regions under consideration (Fig. 1, 1).

The earliest embryos from which blood could be reliably collected were aged 12 days from conception. Many of the fractions of the adult are already present (Fig. 1, 2) but certain interesting differences can be noted. First, fraction 1 (albumin) is present in the early embryos at a very low concentration.

Secondly, fractions 2 and 3 of the adult are absent; but there is a second fraction slower than both the above, and by far stronger than albumin.

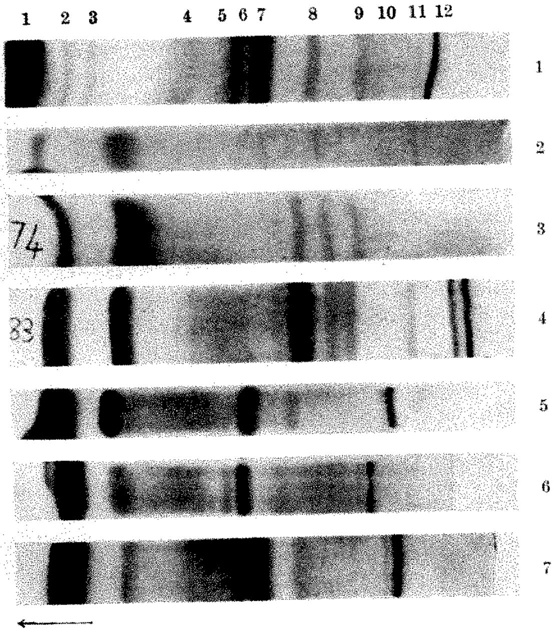

Fig. 1. Starch-gel electrophoresis pattern of plasma proteins of mouse. 1, 15-day pregnant female; 2, 12-day fœtus; 3, 15-day fœtus; 4, 19-day fœtus; 5, new-born; 6, 12-day-old young; 7, 18-day-old young

Thirdly, all other fractions are found in a concentration that is both low and about equal for all, that is, the bands in the transferrin region and the α_2-globulin are not stronger than the others, as in the adult.

The second fraction is still the strongest in the 15-day fœtus (Fig. 1, 3), but by the latter days of intrauterine life (Fig. 1, 4) and in the new born (Fig. 1, 5) albumin equals it in concentration, to exceed it by the twelfth day after birth (Fig. 1, 6).

The single second fraction persists after birth in the young, providing a contrast with the two fractions (2 and 3) of their mothers as tested during pregnancy.

Finally, the transferrin and slow α_2-globulin bands (6, 7, 12) do not reach their typical prominence over other fractions until a few days before birth (Fig. 1, 4).

α-Galactosidase Activity of Rumen Bacteria

In a recent search for bacterial α-galactosidases, Carrere, Lambin and Courtois[1] tested many organisms isolated from the intestinal tracts of a wide range of animals including several ruminants. Only one bacterial species, from the guinea pig, containing α-galactosidase was obtained. The authors commented on the apparent rarity of this enzyme in bacteria, although it is fairly widespread in yeasts and plant tissues[2]. Bacteria producing α-galactosidase might be expected in rumen micro-flora, particularly in animals grazing pasture, as small amounts of oligo- and poly-saccharides containing α-linked galactose are present in many pasture plants. In addition the leaves of plants such as red clover (*Trifolium pratense*) contain up to 1 per cent (dry wt. basis) of lipid bound galactose[3], present either as monosaccharide or 6-*O*-α-D-galactopyranosyl-D-galactose glycosidically joined through a β-link to the lipid glycerol[4]. The ability of rumen bacteria to release this α- and β-linked galactose has not been demonstrated. One rumen organism, *Streptococcus bovis*, appears to be a potential producer of α-galactosidase, as an extract from cells of one strain of this species has been shown able to hydrolyse melibiose[5]. The action of cell extracts from mixed rumen bacteria and *S. bovis* on various compounds containing α-linked galactose has, therefore, been investigated.

Mixed rumen bacteria, freed from protozoa and plant debris by repeated centrifuging, were prepared from the rumen contents of a cow feeding on fresh red clover. *S. bovis* cells (strain I)[6] were collected from cultures grown in a medium[6] containing glucose (2 per cent w/v) as sole carbohydrate. Bacterial cell extracts (25 ml. from 1–2 gm. wet wt. of cells) were prepared in acetate buffer (0·05 *M*, *p*H 6·0) and tested for carbohydrase activity by the procedures described previously[5], all incubations being done at 39° C. Total plant lipids were extracted from fresh cut red clover leaves with boiling 80 per cent (v/v) aqueous ethanol and, after removal of the ethanol, freed from sugars by suspending in water and centrifuging at high speed. Galactose was the only sugar detected after hydrolysis of the lipids in *N*-sulphuric acid for 1 hr. at 100° C. Approximately one-third of the plant lipid galactose in clover lipids is present as the disaccharide[3]. Mono- and di-galactosyl glycerol, prepared from the lipids by alkaline hydrolysis and column chromatography, were supplied by Mr. R. O. Weenink, Fats Research Laboratory, Department of Scientific and Industrial Research, Wellington.

Extracts from the mixed rumen bacteria readily hydrolysed sucrose, maltose, cellobiose, lactose, salicin and mono-galactosyl glycerol. Melibiose and methyl α-D-galactoside were also hydrolysed, but at a much slower rate. With raffinose and stachyose the rapid release of fructose, producing melibiose and manninotriose respectively, was followed by a much slower release of galactose. The di-galactosyl glycerol was also hydrolysed ultimately to galactose and glycerol. Although these results confirm the suggestion that rumen bacteria may serve as a source of α-galactosidase the extracts from the mixed organisms contain too many other carbohydrases to be of any value as an α-galactosidase preparation.

The extracts from the *S. bovis* cells gave a strikingly different pattern of hydrolysis. The following compounds were not hydrolysed: isomaltose, gentiobiose, maltose, cellobiose, lactose, nigerose, turanose, sophorose, α-α-trehalose, sucrose, methyl-α-D-glucoside, salicin, arbutin, rutin, amygdalin and mono-galactosyl glycerol. Melibiose and methyl-α-D-galactoside were, however, readily hydrolysed and galactose was rapidly liberated from di-galactosyl glycerol, raffinose, stachyose and verbascose. With these latter compounds mono-galactosyl glycerol and sucrose, in addition to galactose, were detected as end products of hydrolysis. Raffinose and stachyose could be detected during intermediate stages in the hydrolysis of stachyose and verbascose respectively. It is evident that at least one common, easily cultured, species of rumen bacteria is able to produce an α-galactosidase free from other disaccharidases, particularly invertase and β-galactosidase. Previously[5], when the organism was grown in a sucrose medium to produce dextran, the cell extracts contained invertase and isomaltase, as well as the α-galactosidase.

None of the cell extracts from either source liberated galactose from the plant lipid preparations. When, however, mixed rumen bacteria were incubated, under toluene, with the lipids galactose was liberated. This did not occur with *S. bovis* cells. It is possible that lipolysis must free the mono- and di-galactosyl glycerols before they can be hydrolysed and that *S. bovis* does not contain any lipase.

ε-Lysine Acylase in Bacteria

Although a number of reports have been published on α-amino acylase, little is known about ε-lysine acylase, which hydrolyses ε-*N*-acyllysine. Paik *et al.*[1] first confirmed the activity in rat tissues, and Kameda *et al.*[2] and Wada[3] reported the activity in a micro-organism of *Pseudomonas*. The activities of the enzymes in these reports were very low and the enzymes were not obtained as a pure protein.

We also investigated the distribution of ε-lysine acylase in various micro-organisms in order to obtain a suitable enzyme source for the optical resolution of ε-*N*-benzoyl-DL-lysine, and previously showed that the enzyme is inducibly formed in several moulds, especially in *Aspergillus oryzae*[4]. This mould enzyme, however, showed no optical specificity on the hydrolysis of ε-*N*-acyl-DL-lysine[5].

Investigation has been continued further, and a micro-organism isolated from the soil collected at Nakamura, Kochi Prefecture, has been found to produce very high ε-lysine acylase activity, and purification of this enzyme has been attained. This micro-organism was identified as being *Achromobacter pestifer* by Dr. H. Iizuka, the Institute of Applied Microbiology, University of Tokyo. The type culture of *Achromobacter pestifer* in the Institute, however, shows very low activity, about 1/2,000 of that of the isolated strain. So to make a distinction, the strain isolated by us is named here *Achromobacter pestifer EA*.

In order to obtain the pure enzyme preparation of ε-lysine acylase from the culture of *A. pestifer EA*, the micro-organism was cultured under aerobic condition in a jar-fermenter at 30° C. for 24 hr. The medium used had the following composition: glucose 5 per cent, peptone 1 per cent, potassium biphosphate 0·2 per cent and magnesium sulphate 0·1 per cent, and the *p*H was adjusted to 7·0.

The cells collected by centrifugation were autolysed with the addition of toluene and extracted with *M*/15 sodium sulphate solution. The extract was purified by the following procedures: the first ammonium sulphate fractionation (45–70 per cent saturation), 0·3 per cent rivanol treatment, acetone fractionation (45–60 per cent volume), the second ammonium sulphate fractionation (48–60 per cent saturation), and fractionation with vertical zone electrophoresis. The electrophoresis was carried out on a methanolysed cellulose powder with a veronal buffer of 0·0505 ionic strength, *p*H 8·8, in the apparatus designed by Chiba *et al.*[6], which enables extensive electrophoresis without electro-osmosis. A potential of 300 V. (20 m.amp) was applied for 160 hr. at 6° C. On completion of the run, the column was eluted with the same buffer as described here. Enzyme activity and protein concentration of the respective fractions collected in test-tubes were measured. As shown in Fig. 1, the enzyme activity only occurs at the main peak of the protein concentration curve, and the specific enzyme activities of fractions No. 26–34 are coincidental, that is, 15,000 lysine μmoles/hr./mgm. of protein are obtained through the fractions, when ε-*N*-benzoyl-L-lysine is used as the substrate. Accordingly, it is obvious that these fractions consist of a single enzyme protein, and this is first the isolation of ε-lysine acylase in pure form.

By comparing ε-lysine acylase activities of various enzyme sources, as shown in Table 1, it is apparent that the activity of *A. pestifer EA* is the highest ever reported.

Table 1. ε-LYSINE ACYLASE ACTIVITY OF VARIOUS ENZYME SOURCES

Enzyme sources	Enzyme activity* Crude extract	Purified preparation	Optimum *p*H	Ref.
Rat kidney	0·023	2·59	7·0	(1)
Pseudomonas (*KT*83)	0·32	1,190	6·0	(3)
Aspergillus oryzae No. 10	2·90	31·6	8·2 ~ 8·4	(5)
Achromobacter pestifer EA	240	15,000	5·0	(†)

* Liberated lysine micromoles/hr./mgm. of protein.
† Present communication.

With this pure preparation the enzymatic properties of bacterial ε-lysine acylase were investigated. In the absorption of ultra-violet light the enzyme showed $E^{1\%}_{1\text{cm.}}$ (280 mμ) 12·00 and $E_{280/260}$ 1·84. The *p*H optimum was 5·0 in acetate or veronal buffers. The activation energy was 9,280 cal.

The enzyme was inhibited by heavy metal ions, Ag^+, Hg^+ and Hg^{++}, and by SH-inhibitors such as monoiodoacetic acid, ω-chloroacetophenone and *p*-chloromercuribenzoate. Since the inhibition due to the last-mentioned agent was completely overcome by

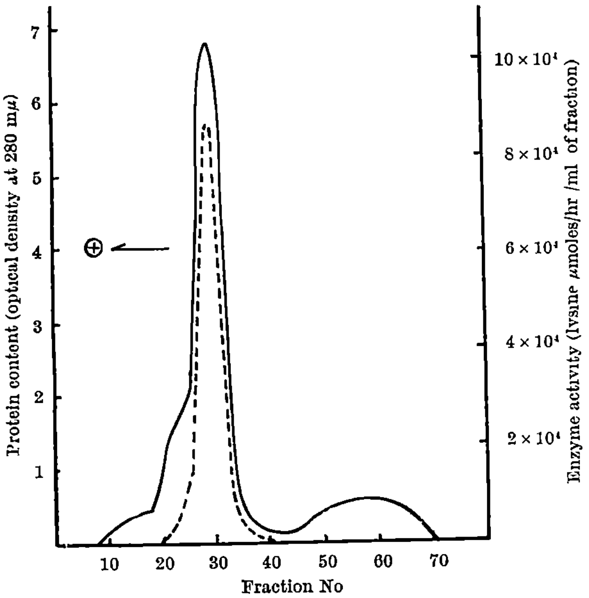

Fig 1 Zone electrophoresis The protein content of each fraction was calculated from the optical density at 280 mμ The enzyme activity of each fraction was measured as follows a mixture of 0 5 ml of $M/10$ acetate buffer (pH 5 0), 0 5 ml of 0 012 M ε-N-benzoyl-L-lysine solution and 0 5 ml of appropriately diluted fraction was incubated at 42° C for 10 min , and the liberated lysine was measured by Work's acidic colorimetric ninhydrin method ——, Protein content, – – –, enzyme activity

the addition of cysteine, the enzyme is considered to be an SH-enzyme

The influence of various di- and tri-valent metal ions on the activity of the enzyme was also investigated But none of the metal ions tested enhanced the activity, as observed in Co^{++} in the case of α-amino acylase With regard to the influence of various metal chelating agents, although the inhibition by ethylenediamine tetraacetic acid and citrate was very slight, addition of oxalate or pyrophosphate inhibited considerably the activity of the enzyme However, the enzyme solution inactivated by the presence of the chelating agents was completely restored to activity after dialysis towards the buffer solution containing no chelating agents

In order to clarify the specificity of the enzyme, various N-acyl derivatives of lysine and its analogues were synthesized, and the susceptibility towards this bacterial ε-lysine acylase was investigated The enzyme shows optical specificity and ε-N-benzoyl-L-lysine is readily hydrolysed, although D-isomer is not hydrolysed The compounds containing no α-amino group, such as ε-N-acylaminocaproic acids and ε-N-benzoylamino-α-halogenocaproic acids, also α-N-acyl and α,ε-N-diacyl derivatives of lysine, are not susceptible to the enzyme The compounds having no free carboxyl group, such as monobenzoylcadaverine, ester and amide derivatives of ε-N-benzoyl-L-lysine, are not hydrolysed by this enzyme

The above results suggest that a free α-amino group and a free carboxyl group are required for the substrate to be hydrolysed by this bacterial enzyme As the homologues of ε-benzoyllysine, δ-N-benzoyl-L-ornithine and ζ-N-benzoyl-DL-homolysine are unsusceptible, the carbon chain of the substrate also shows a significant effect on this enzyme reaction Accordingly, the bacterial ε-lysine acylase has a higher substrate specificity than α-amino acylase, and susceptible substrate is limited to ε-N-acyllysines Among the ε-N-acyllysines, the hydrolytic rate decreases in the order benzoyl > monochloroacetyl > acetyl

As the asymmetric hydrolytic activity of this bacterial enzyme is very high, the enzyme produced by *A pestifer EA* can be used for the optical resolution of ε-N-acyl-DL-lysine

Biosynthesis of Valine and Isoleucine in the Wheat Plant

As valine and isoleucine are essential amino-acids for animal organism, the mechanism of their biosynthesis in higher plants is of importance Experiments carried out with micro-organisms have shown that the two final steps in biosynthesis of valine and isoleucine are based on the dehydration of their α,β-dihydroxy-analogues to α-keto-analogues, which are further metabolized by transamination[1]

Our experiments on the biosynthesis of valine and isoleucine were carried out with ripening wheat ears, green wheat seedlings, seedlings of other plants and homogenates of green seedlings Keto-analogues of valine and isoleucine (α-keto-isovaleric and α-keto-β-methyl-n-valeric acids respectively) were synthesized in the form of sodium salts by the methods described by one of us[2,3] Quantitative analysis of amino-acids was carried out by paper chromatography technique[4 5] Asparagine was determined by acid hydrolysis followed by quantitative chromatography of the resulting aspartic acid[6] The keto-analogue of isoleucine was determined by quantitative paper chromatography of its 2,4-dinitrophenylhydrazone A mixture of *tert* butanol/ethanol/water (50 10 50) was used as solvent[6]

We have shown[7] that the introduction of the keto-analogues of valine and isoleucine (0 05 M solutions) into ripening wheat ears through the transpiration current of the stem results in accumulation (in 10 hr) of considerable quantities of valine and isoleucine respectively The synthesis of valine and isoleucine is accompanied by the decrease in glutamic acid, alanine and to some extent glutamine

Acid ammonium phosphate introduced into wheat ears exerted no stimulating effect on the synthesis of valine and isoleucine from their keto-analogues but played the part of some 'preserving factor' of the amino-acids already mentioned and glutamine On introduction of these keto-analogues, accumulation of γ-aminobutyric acid was observed

The keto-analogue of valine being introduced into green wheat seedlings was readily transformed into valine[8] The synthesis of γ-aminobutyric acid also probably plays some important part in the nitrogen metabolism of plants[9] Here, the synthesis of valine was accompanied by decrease in more sets of different amino-acids than in the case of the synthesis of valine from its keto-analogue in wheat ears (decrease in glutamic acid, serine, glutamine, asparagine, alanine and isoleucine has been observed) The rate of the synthesis of valine from its keto-analogue in the dark was as high as in the light As in the case of the experiments with wheat ears, introduction of acid ammonium phosphate exerted no stimulating effect on the synthesis of valine from its keto-analogue, but it showed 'preserving activity' on the amino-acids and amides already mentioned

The results obtained show that the processes of biosynthesis of valine and isoleucine from their keto-analogues in ripening wheat ears as well as in green wheat seedlings are brought by transamination of these keto-acids with different amino-acids and amides

It has been shown that the keto- and dihydroxy-analogues of isoleucine introduced into green wheat seedlings[6] by vacuum infiltration are readily transformed into isoleucine The synthesis of isoleucine is accompanied by decrease in several amino-acids (glutamic and aspartic acids, alanine, serine and glutamine) present in the seedlings These observations indicate the contribution of transamination reaction to the biosynthesis of isoleucine Acid ammonium phosphate had no stimulative effect on the biosynthesis of isoleucine Infiltration into the plant of the dihydroxy-analogue of isoleucine brought about the synthesis not only of isoleucine, but also of some other amino-acids (phenylalanine, γ-amino-butyric acid threonine) The substrates being introduced into the green plant undergo conversion not only into the compounds of which they are the direct precursors, but also into other different compounds which are products of their metabolic transformation Identical results were obtained by Kretovich and Uspenskaya[4,5], in their work on the biosynthesis in plants of phenylalanine from phenylpyruvate

Table 1 FORMATION OF THE KETO-ANALOGUE OF ISOLEUCINE (α-KETO-β-METHYL-*n*-VALERIC ACID) FROM THE DIHYDROXY-ANALOGUE (α,β-DIHYDROXY-β-METHYL-*n*-VALERIC ACID) IN HOMOGENATES FROM WHEAT SEEDLINGS

No	Final *p*H	Total nitrogen in sample (mgm)	α,β-Dihydroxy-analogue of isoleucine added	α-β-Dihydroxy-analogue of isoleucine + $(NH_4)_2HPO_4$ added
1	7 7	9 1	15 5	14 9
2	7 1	11 9	7 8	10 8
3	7 5	15 5	12 0	13 5

5 0 ml of homogenate from wheat seedlings in 0 067 *M* phosphate buffer incubated with different substrates (final concentration 0 025 *M*) for 5 hr at 30° Keto-analogue of isoleucine, μmoles/5 0 ml (125 μmoles of substrates)

In homogenates from green wheat seedlings the synthesis of isoleucine was weak and was possible only from its keto-analogue Thus the destruction of plant cell structure decreased the rate of transamination processes, in the case when the dihydroxy-analogue of isoleucine was added to the homogenate, considerable quantities of its keto-analogue were formed (Table 1) These results indicate that in homogenates from green wheat seedlings the dihydroxy-analogue of isoleucine is readily transformed into its keto-analogue, which proves the presence of a very active dehydrase of dihydroxy acids, found previously only in micro-organisms[10-12]

From the results obtained, we concluded that the two last steps of biosynthesis of valine and isoleucine in green plants are identical with those in micro-organisms, that is, dihydroxy-analogues are dehydrated to keto-analogues, the latter being further metabolized by transamination

From this point of view, the results of Wixom and Wikman[13] are of interest They found that in a diet for young rats valine can successfully be replaced by its keto-analogue, but not by its dihydroxy-analogue In homogenates from liver of those rats these authors failed to detect dehydrase of dihydroxy acids

As we have shown[7] in homogenates from liver of mice the keto-analogues of valine and isoleucine are readily transaminated with glutamic acid

On the other hand, in different animal organs, particularly in mice liver, there exists reductase of α-keto-β-hydroxy acids, the enzyme catalyses the reduction of α-keto-β-hydroxy-isovaleric and α-keto-β-hydroxy-β-methyl-*n*-valeric acids to dihydroxy-analogues of valine and isoleucine respectively[14]

Our results, as well as those of the aforementioned authors[13 14], suggest that the mechanism of necessity of valine and isoleucine for the animal organism is connected with the absence of the dehydrase of dihydroxy acids

PHYSIOLOGY

Diurnal Periodicity in Epiphyseal Growth Cartilage

IN order to utilize radiotracers effectively, in an examination of bone cells, it became desirable to determine if the mitotic event was subject to the same diurnal changes observed for many other tissues[1] The young proliferating cartilage epiphyseal plate served as a model since (*a*) the zones in which mitotic activity occur are well defined, (*b*) the tissue homogeneity obviates problems of cell identification which obtain in metaphyseal bone Two 'spot-checks' of serially independent groups of animals were made during a single 24-hr period utilizing the colchicine method

Thirty one-month-old CF_1 mice weighing 13–18 gm were singly housed and maintained under controlled conditions of temperature (78° ± 1° F) and light for a period of 9 days prior to experimentation, the photoperiod has been shown to be critical for the stability of periodic phenomena[2] The room was illuminated from 09 00 until 21 00 alternating with 12 hr of darkness Intentional disturbance was limited to 09 00–09 30 when the animals were attended to minimize the event of extraneous stress Day (02 00–10 00) and night (15 00–23 00) groups, each consisting of 15 mice, males and females, were injected with 0 1 mgm /100 gm body-weight colchicine subcutaneously 7 hr before death

The hind limbs were dissected out and the knee joints were fixed in neutral formalin, decalcified in a buffered sodium formate–formic acid solution, embedded in celloidin or paraffin, sectioned longitudinally at 10μ and the sections were stained with iron hæmatoxylin or hæmatoxylin and eosin The number of c-metaphase figures appearing in all regions of the proliferative zones of the distal femoral and proximal tibial epiphyseal cartilages was counted under an oil immersion lens by an ocular grid at a magnification of × 970 Two hundred fields, or about 4,000 cells, were observed, the number of metaphase arrests was tabulated as an average value for 1,000 cells

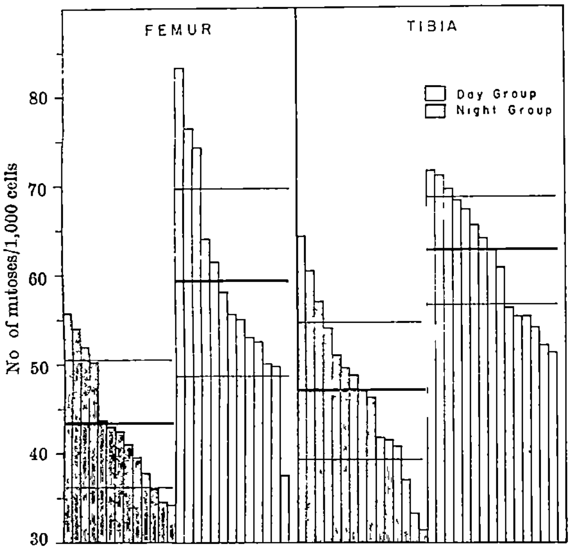

Fig 1 Plot of the individual variation in the day and night groups showing the shift in mitotic rhythm The horizontal lines denote the mean and the range of standard deviations

The number of c-metaphases in the proliferative zones of the knee joint cartilages has been plotted individually in Fig 1 Only 13 values for the distal femoral cartilage in each group were recorded owing to the failure to obtain reliable sections in four instances The broad amplitude of individual scores in both groups is perhaps due in part to the difficulty with which mitotic figures in the long, narrow cells of the most actively proliferating zones of the cartilages may be discerned, and the values overlap somewhat From the mean values obtained, the distal femoral and proximal tibial cartilages grow roughly 26 8 and 23 3 per cent faster during the day than during the night respectively Similarly, the growth of the tibial cartilage exceeds that of the femur by 7 7 and 5 3 per cent at these times Approximately 20 0–23 1 per cent of the individuals consistently lie above the standard deviation, and for a given tissue, the percentages are coincident, the ratio between the number of individuals falling within and below the limits of the standard deviation is, however, more variable Although deletion of the lowest value for the day femurs would eliminate the overlapping standard deviations, a microstatistical analysis of the extreme outliers indicates that these derive from the same population[3]

The preliminary findings indicate that a diurnal periodicity exists for the cells of the young growing epiphyseal cartilages of mice which is similar to that of most tissues other than the adrenal cortex It is, however, impossible to estimate the actual hour of maximum and minimum proliferative activity since colchicine operates by accumulating mitoses in metaphase arrest More exhaustive studies involving intermediate time-periods would be necessary for precise information[1] In view of collateral information that adrenalectomized animals (*a*) fail to evidence marked diurnal rhythms, and (*b*) evidence stimulated chondrogenesis leading to thicker cartilage plates[5], it may be suggested that the day–night differences here reflect the cyclic secretory activity of the adrenal cortex Since serum corticosterone should be minimal at 11 00 under the photoperiod utilized, proliferative activity of the cartilages might be expected to increase towards the onset of the light period with additional increments throughout the first half of the period

This investigation was supported in part by a research fellowship (*DF* 12,985) from the National Institute of Dental Research, U S Public Health Service

Effect of Dinitrophenol on Active Relaxation of Unstriated Muscle

SOME unstriated muscles, such as those of guinea pig uterus and frog stomach muscle, relax without the application of any external force when treated with adrenaline[1–3], during such relaxation the oxygen consumption increases[4] Relaxation is prevented if these muscles are previously asphyxiated or treated with cyanide and can be partially restored with glucose Asphyxia or cyanide causes relaxation of loaded muscle On the basis of these experiments it has been suggested that unstriated muscle contains two contractile mechanisms One is responsible for the phasic response and a kind of tone susceptible to asphyxia and relaxes passively, the other is responsible for the asphyxia-resistant tone, relaxes actively and thus is able to maintain contraction or tension without expenditure of energy

Dinitrophenol is known to uncouple respiratory oxidation from adenosine triphosphate formation and it has interesting effects on the relaxation of frog's stomach muscle In unloaded muscle, dinitrophenol (0 2 mM–0 5 mM) completely prevents the relaxation by adrenaline, 10^{-6}–10^{-5}, the control muscles relaxing by 23–40 per cent in 15 min at room temperature, 25 to 30° C (10 experiments) The loaded muscle is at first completely relaxed by dinitrophenol; after 1–2 hr , it may then contract, and the contraction is unaffected by adrenaline, asphyxia or cyanide This asphyxia-resistant contraction by dinitrophenol is favoured by keeping the *p*H of the saline at 6 5 (phosphate buffer) Thus formation of adenosine triphosphate is necessary not only for relaxation, but also for keeping the muscle relaxed

Toxicity of Endotoxin and Snake Venom in the Hagfish

REACTIONS to parenteral administration of endotoxin in mammals include pyrexia, leukopænia followed by leukocytosis, vasodilation, and irreversible shock[1] Spink[2] reviewed the actions of snake venom and endotoxin, and concluded that their mechanism of action is similar, however, in recent studies Condie *et al* [3] showed that there are few parallels between the biological responses of rabbits to *Escherichia coli* endotoxin and *Agkistrodon piscivorus* venom and that the two toxins are distinct immunochemically

Stetson[4] postulated that the reactions to endotoxin may reflect hypersensitivity in animals the enteric flora of which include Gram-negative organisms Since earlier studies[5] in the California hagfish, ***Eptatretus stoutii***, indicated that this primitive vertebrate is essentially anergic and unable to develop either immediate or delayed hypersensitivity to bacterial or virus antigens, we felt that a comparison of the toxic action of snake venom and endotoxin in this species would be of interest

Freshly obtained California hagfish, weighing 30–80 gm, were kept in well-aerated sea-water, maintained at 10° C, for a preliminary 24-hr observation period, and then divided into groups of two animals per dose of toxin The doses of *Agkistrodon piscivorus* (water moccasin) and *Naja flava* (yellow cobra) venoms and *Escherichia coli* endotoxin were made up to 2 ml volumes in 0 9 per cent saline and injected into the subdermal lateral sinuses in the tail region of the fish, anterior to the caudal heart This approximated an intravenous injection in this animal, which has an intermediate-type open circulation, with return vessels similar to *Amphioxus* Ten-fold variations in dosage were studied (Table 1), and dramatic differences in response to endotoxin and snake venoms were noted

Endotoxin, even in the 100 mgm dose, failed to produce a detectable reaction in the hagfish, and the animals remained coiled up, their normal attitude when undisturbed There were no observable differences between these endotoxin-treated fish and the control animals receiving 2 ml of 0 9 per cent saline By contrast, all doses of the venoms, except 1 mgm of *Agkistrodon piscivorus* venom, were lethal within 5 hr, and the highest doses produced death within 30 min The dying animals uncoiled to a straightened position, and swimming movements stopped The complete suppression of these movements suggests action of the venom on the nervous system, since Campbell[6] has shown that swimming movements of segments continue after the hagfish spinal cord is sectioned The isolated aneural heart of the hagfish has been studied by one of us (D J)[7], and the effects of snake venom on this organ are now being tested and will be reported later

Table 1 RESPONSE TO ENDOTOXIN AND SNAKE VENOMS IN THE HAGFISH

Toxin dose	Deaths* 1 hr	24 hr	48 hr
Agkistrodon piscivorus venom (mgm)			
1	0/2	0/2	0/2
10	0/2	2/2	—
100	2/2	—	—
Naja flava venom (γ)			
50	2/2	—	—
100	2/2	—	—
1,000	2/2	—	—
Escherichia coli endotoxin (mgm)			
1	0/2	0/2	0/2
10	0/2	0/2	0/2
100	0/2	0/2	0/2

* No of deaths within the period specified after administration of the toxin

Table 2 RESPONSE TO ENDOTOXIN AND SNAKE VENOMS IN THE RABBIT (1 KGM)

Toxin dose	Deaths* 1 hr	24 hr	48 hr
Agkistrodon piscivorus venom (mgm)			
1	1/5	1/5	1/5
10	9/10	9/10	9/10
Naja flava venom (γ)			
100	0/10	0/10	0/10
200	0/4	4/4	—
500	0/4	4/4	—
Escherichia coli endotoxin (mgm)			
1	1/20	1/20	1/20
10	2/5	3/5	4/5
100	1/3	1/3	2/3

* No of deaths within the period specified after administration of the toxin

That a 100-mgm dose of endotoxin was without effect in these animals is of interest when compared to the effect in rabbits (Table 2) The dose in the hagfish is equivalent to about 1 5 gm/kgm, and the consistent lethal effect of 1/10, and often of 1/100, of that amount in rabbits is important in dissociating the activities of endotoxin and snake venom

The hagfish may be immune to endotoxin because of unknown natural or tissue inhibitors Alternatively, they may be able to break endotoxins down to less toxic materials However, in view of the extremely high doses of endotoxin used in this study, we believe that these hypotheses are less attractive than the Stetson theory that reactions to endotoxin in mammals are a result of hypersensitivity to the products of gut tract flora This hypothesis could be tested further in germ-free mammals using toxins and dosages comparable with those used in this work

These investigations were aided by grants from the U S Public Health Service, American Heart Association, Minnesota Heart Association and the National Foundation

PHARMACOLOGY

Inhibition of Ascites Tumour Growth by the Trypanocide, Ethidium Bromide, in Combination with Azaserine

Ethidium bromide (3,8-diamino-5-ethyl-6-phenyl-phenanthridinium bromide) has been used to treat trypanosome infections of cattle in Africa for some time[1,2]. (This chemical was kindly supplied by Dr. M. R. Gurd, Boots Pure Drug Co., Ltd., Nottingham. Its alternative name is 2,7-diamino-9-phenyl-10-ethyl-phenanthridinium bromide.) Recently we have examined the biochemical effects of this compound on Ehrlich ascites tumour cells, and have found that it inhibits completely the incorporation of preformed purines (adenine, guanine and hypoxanthine) into nucleic acids[3]. The possible application of this biochemical effect to cancer chemotherapy was immediately considered. It was believed, however, that ethidium bromide, if used alone, would at best be only moderately carcinostatic because it does not appreciably impair the *de novo* pathway of purine biosynthesis[3]. Because the antibiotic azaserine is well known to inhibit completely the *de novo* synthesis of purines, it was therefore believed that if these two compounds could be used in combination without undue host toxicity, the conditions for a complete concurrent blockade[4] of the purine nucleotide supply for nucleic acid synthesis could be effected. Because both drugs maintain their inhibitory effects for less than 24 hr.[3,5], for more nearly maximal effect it was felt that both should be administered more often than in the daily treatment schedule usually used in tests of carcinostatic efficacy.

Female Swiss mice, 26–28 gm., were inoculated intraperitoneally with approximately 1 × 10^6 Ehrlich ascites carcinoma cells (hypotetraploid line). Morning and evening drug treatments were begun the following day and continued for 6 days. The mice were weighed at the beginning and end of this period. Both drugs were administered in solution in isotonic saline, and control groups received saline injections. The experiments were terminated 50 days after tumour implantation, and the average survival times calculated. All animals alive at 50 days were considered to be 50-day survivors in calculating the average survival-time. The animals received food and water *ad lib.* Averaged results from two experiments are presented in Table 1.

Table 1. Treatment of Ehrlich Ascites Tumours with Combinations of Ethidium Bromide and Azaserine

Dose (mgm./kgm.) Ethidium bromide	Dose (mgm./kgm.) Azaserine	Average survival-time (days)	50-day survivors/total No. of animals	Average weight change (gm.)
0	0	8.9 ± 1.9*	0/14	+ 6.2
0	0.1	17.5 ± 1.8	0/14	+ 2.0
4	0	11.8 ± 3.8	0/14	− 1.1
3	0	12.5 ± 3.4	0/14	+ 2.2
4	0.1	34.8 ± 8.3 (31.8)†	7/14	− 1.6
3	0.1	26.7 ± 9.7 (23.6)†	6/14	+ 1.2

* Average deviation from the mean.

† Numbers in parentheses are the average survival-times of the animals which did not survive 50 days.

Ethidium bromide prolonged survival-time slightly if at all at a dose of 4 mgm./kgm., which was the highest dose which could be given on this treatment schedule without excessive weight loss or death[3]. The combination of azaserine with this dose of ethidium bromide, however, increased survival-time almost 400 per cent, which clearly indicates potentiative action. Of particular interest was the finding that half the mice so treated survived 50 days and were free of gross tumour growth at that time.

To our knowledge, phenanthridinium compounds have not previously been shown to have carcinostatic properties, alone or in combination with other drugs. It is hoped that the carcinostatic effects of ethidium bromide will be examined in more detail, and that closely related compounds will be examined for their biochemical and biological effects.

Inhibition of Release of Corticotrophin

Most present concepts of the mechanism of stress activation of the adenohypophysis include the idea of neuro-endocrine 'releasing factors' which liberate a portion of the stored preformed corticotrophin[1]. In contrast to the depletion of corticotrophin demonstrated by Rochefort *et al.*[2] during prolonged stresses we have not been able to demonstrate any depletion after stress of short duration during the period of marked elevation of circulating corticotrophin. In adrenalectomized animals, there is actually an elevation of adenohypophyseal corticotrophin content coincident with the period of peak blood-level of corticotrophin[3]. This has led us to consider that, in the pituitary, stimulation of biosynthesis of corticotrophin is a very important element in the response to acute stresses. For this reason, we felt that it might be of interest to determine whether a blockade of corticotrophin biosynthesis would have any effect on the subsequent ability to release this hormone. We examined the effect of ethionine pre-treatment upon the stress-induced secretion of corticotrophin in rats.

D,L-ethionine (25 mgm./c.c. in saline) was administered subcutaneously in doses of 50 mgm. to groups of 150 gm. female Wistar rats. At various time-intervals after this treatment, the rats were stressed by 1 min. of ether anæsthesia followed by sham unilateral adrenalectomy. At 2.5 min. following the onset of the stress, the rats were decapitated, bled, and the mixed trunk blood assayed for corticotrophin activity by measuring adrenal ascorbic acid depletion according to the method of Hodges and Vernikos[4]. Control groups were pre-treated with saline or with ethionine plus a small molar excess of methionine.

This experiment (Table 1) demonstrates clearly the inhibitory action of ethionine on the acute secretion of corticotrophin after stress. The inhibition is well established in as short a time as 1 hr. of pre-treatment,

Table 1 CORTICOTROPHIN ACTIVITY IN THE BLOOD OF ETHIONINE-TREATED RATS 2 5 MIN AFTER STRESS

(Figures in parentheses are the number of animals in each treatment or assay group Adrenal ascorbic acid of saline-injected assay rats was 546 ± 11 mgm /100 gm adrenal tissue)

Treatment and time prior to stress	Adrenal ascorbic acid depletion activity of blood mgm /100 gm adrenal tissue ± *S E*
Saline 2 ml s c 3 hr (6)	110 ± 11 (6)
Ethionine 50 mgm s c 1 hr (6)	23 ± 16 (6)
Ethionine 50 mgm s c 3 hr (6)	21 ± 17 (6)
Ethionine 50 mgm and Methionine 60 mgm s c 3 hr (6)	109 ± 17 (6)

and is present as long as 3 hr after a single dose of ethionine That the effect is due to the biological antagonism of ethionine for methionine is shown by the complete reversal of the blockade when the normal agonist is administered along with the antagonist The dose and time relationships of this inhibition are subjects of active investigation

The use of amino-acid antagonists offers a new means of investigating the dynamic aspects of corticotrophin synthesis and release Since such marked inhibition of release of corticotrophin is produced by pre-treatment with ethionine, we are encouraged to believe that synthesis of new hormone may be essential for the normal response of the adenohypophysis to mild stresses of short duration

HÆMATOLOGY

Distribution of the Serum Group-Specific Components in Israel

THE group-specific components (*Gc*) of human sera, described in 1959 by Hirschfeld[1], constitute a system of α_2-globulins varying in relative electrophoretic mobilities Family studies disclosed that this system is controlled by two co-dominant autosomal alleles, Gc^1 and Gc^2 (refs 2 and 3) Three common phenotypes can be distinguished by immunoelectrophoresis as indicated by the different position and shape of the *Gc*-precipitates a fast-moving component (*Gc* 1–1), and a slow-moving component (*Gc* 2–2) correspond to the homozygous types, the heterozygous type is characterized by the presence of both components forming an extended, two-peaked precipitate (*Gc* 2–1) Population surveys have revealed considerable variations in the distribution of *Gc* allele frequencies in different geographical areas and ethnic groups The frequencies of Gc^2 varied from 0 306 in Indians (Bombay) to 0 023 in a population of Navajo Indians[4,5] In the various Jewish populations in Israel the distribution of several genetic traits has been extensively investigated Differences in the distribution of blood groups[6], and incidence of erythrocyte glucose-6-phosphate dehydrogenase deficiency[7], have been demonstrated The differences demonstrated in the distribution of haptoglobins were not statistically significant Significant differences in the taste sensitivity to phenylthiourea were found only in males The present investigation is concerned with the distribution of the group specific components among various populations in Israel

388 sera were obtained at the Tel-Hashomer Government Hospital from blood donors and patients without serious illness The material consisted of unrelated individuals of different Jewish populations 99 Ashkenasi Jews (European origin), 64 North African Jews (Morocco, Tunisia, Algeria and Libya), 49 Persian Jews, 85 Iraqi Jews, 49 Yemenite Jews and 42 Kurdish Jews 48 sera from unrelated, apparently healthy Arabs were collected in villages in the area of Tel-Hashomer The samples were examined by immunoelectrophoresis according to Scheidegger[8], modified by Hirschfeld[9], using a voltage gradient of approximately 7 V /cm for 120 min The antiserum used in this work was the horse antiserum No 13411 against normal human serum from the Pasteur Institute, Paris

The distribution of the group-specific component in the Israeli populations studied is shown in Table 1 The frequencies for Gc^2 varied from 0 338 in Ashkenazi to 0 190 in Kurdish Jews The frequency of Gc^2 in a small sample of Arabs was found to be within this range, 0 260 The Gc^2 frequency of 0 338 in Ashkenasi Jews is the highest incidence of Gc^2 observed in a population thus far The distribution of *Gc* genotypes in the populations studied was in agreement with the expected distribution based on the Hardy–Weinberg equilibrium Statistical analysis by heterogeneity-χ^2-tests, applying Yates correction for small samples, did not reveal significant differences within the various Jewish populations However, if the material is analysed by comparing the Ashkenasi

Effects of Fibrin Surface on Coagulation of Blood

RECENT reports[1,2] suggest that fibrin surfaces have an anticoagulant effect. One theory[3] concerning blood coagulation proposes a continuous physiological process of intravascular fibrin deposition and spontaneous lysis. If a fibrin surface is anticoagulant and if the vessels are normally lined with a thin fibrin layer, the therapeutic use of fibrinolytic agents in the treatment of thrombosis might result in the undesired effect of increasing blood coagulability. These considerations led us to re-investigate the *in vitro* effects of fibrin on blood coagulation. The results demonstrate that fibrin has no clot-inhibiting effect but rather a clot-promoting action similar to 'foreign effect' of glass[4,5].

In the first experiment 3-ml. aliquots of normal citrated plasma, prepared from blood in contact with plastic (polystyrene) or siliconed surfaces only, were incubated (37° C.) for 30 min. in plastic tubes with (1) nothing, (2) 300 mgm. 'Pyrex' glass powder, (3) 100 mgm. many times washed human fibrin. After incubation the tubes were centrifuged and duplicate 0.2-ml. samples transferred to 12 × 75 polystyrene tubes and recalcified by addition of 0.2 ml. 0.025 *M* calcium chloride. Table 1 demonstrates that pretreatment with glass or fibrin shortens the recalcification time but does not affect the prothrombin or plasma-thrombin times.

Table 1. EFFECTS OF FIBRIN AND GLASS TREATMENT ON THE SUBSEQUENT CLOTTING OF PLASMA IN POLYSTYRENE TUBES

Preliminary treatment	Clotting time in polystyrene tubes (sec.)		
	Recalcification time	Prothrombin time	Thrombin time
None	440	14.2	21.2
Fibrin	155	14.1	21.4
Glass	197	14.1	21.4

The second experiment attempted a reproduction of Copley's observations[2]. 10 ml. 5 per cent solution of bovine fibrinogen (Armour-Fraction I) was clotted in a 600 ml. beaker by addition of 1 ml. bovine thrombin (5 units). The clot was dried overnight at 37° C., the residue scrapped into a fine powder and 30 mgm. placed in each of eight 13 × 100 glass tubes. Tubes 1 and 2 were washed repeatedly with water and saline, then drained. Tubes 3 and 4 were washed with water and the fibrin residue redried. Tubes 5 and 6 contained dry unwashed fibrin, tubes 7 and 8 wet unwashed fibrin. Tubes 9 and 10 were empty glass and 11 and 12 empty silicone-treated glass. Fresh blood (silicone technique) was added in 0.5 ml. amounts to each tube, the contents mixed as well as possible with a brief shaking and clotting times at 37° C. recorded. Table 2 shows that unwashed fibrin had a marked anticoagulant effect which could be readily overcome by the addition of calcium. Washed fibrin, on the other hand, had no effect on blood coagulation in glass tubes.

Table 2. CLOTTING TIME (SEC.) WHOLE BLOOD PLUS FIBRIN

Tube No.	1 and 2	3 and 4	5–8	9 and 10	11 and 12
Clotting time	240	232	> 7,200*	230	540

* After 2 hr., 0.2 ml. 0.025 *M* calcium chloride added; all tubes clotted.

These experiments show that washed fibrin was not anticoagulant and, in fact, might enhance coagulation in much the same fashion as a glass surface. Such clot-promoting effect could be due to the fibrin surface *per se* or to the adsorption of activated Hageman factor or other clot accelerator on the fibrin.

Table 3. Clotting times (sec.) of 1.5 ml. normal whole blood (silicone technique) in polystyrene tubes containing (*a*) 30 mgm. washed human fibrin, (*b*) 30 mgm. of the same fibrin, first suspended in water in a boiling waterbath for 10 min., then dried and reground, (*c*) an equivalent volume of powdered glass, (*d*) nothing

Clotting time (sec.) 37° C.			
Fibrin	Fibrin—100° C.	Glass	Nothing
405	510	330	1,950

In the next experiment fibrin powder was 'inactivated' by heat. Table 3 shows that even after heating at 100° C. fibrin powder has a coagulant effect. The heat-treated fibrin was more granular than native fibrin and proved difficult to pulverize finely.

In the last experiment fibrin powders were prepared from patients' plasmas deficient in Hageman factor, antihæmophilic factor (AHF) and plasma thromboplastin component (PTC) and their effects compared to normal fibrin and glass. As shown in Table 4, all fibrins had an equal clot-promoting effect.

Table 4. Clotting times of 1.5 ml. normal whole blood (silicone technique) in plastic tubes containing the twelve-times washed, dried and pulverized fibrins derived from 10-ml. citrated plasma samples

	Clotting time (sec.) 25° C.					
Fibrins	Hageman	AHF	PTC	Normal	Glass	Nothing
	600	600	600	600	445	2,040

The coagulation time of whole blood is markedly affected by surface contact. Blood in contact with uninjured endothelium clots extremely slowly if at all. Shed blood in contact with skin, glass or other surface clots, the rate being dependent on the nature of the surface. It is difficult, therefore, to define an 'anticoagulant effect' unless surface exposure is constant. In these experiments it is clear that unwashed bovine fraction I is anticoagulant and that this effect is associated with the citrate content of this fraction as the anticoagulant action can be readily corrected by addition of calcium chloride. On the other hand, washed fibrin does not affect coagulation in glass tubes but accelerates the clotting of blood exposed only to plastic or silicone-treated surfaces This appears to be due simply to a foreign surface effect[4,5] and not to contamination with any serum clot accelerator

This investigation was supported by research grants (*H*–2254) from the Division of Research Grants of the National Institutes of Health, U S Public Health Service, and from the Pittsburgh Health Research and Services Foundation (*A*–48)

PATHOLOGY

A Thymus Responsive Phase in Leukæmogenesis in *AKR* Mice

Endocrine tumours can be produced in animals by disturbing the hormonal balance so that an unbalanced, and abnormally strong, proliferative stimulus impinges on the target endocrine organ During the development of these tumours, three phases can be shown to occur Initially the tumour cells are dependent for their survival on the continued presence of the abnormal environmental stimuli (dependent phase) There follows a phase when the cells are no longer dependent for their survival on such stimuli but will grow more rapidly in the presence of such stimuli (responsive phase) Finally the tumour cells proliferate equally rapidly in the presence or absence of specific environmental stimuli (autonomous phase)[1]

In mice of the high-leukæmia strain, *AKR*, deaths from lymphoid leukæmia commence after the age of 6–7 months It was initially demonstrated by McEndy *et al* [2] that thymectomy in 6-week-old *AKR* mice greatly reduced the subsequent incidence of lymphoid leukæmia This effect was shown to be due, in part at least, to a non-cellular influence exerted by the thymus on lymphoid cells, rendering them susceptible to leukæmogenesis[3] Once leukæmia developed in *AKR* mice, the leukæmic cells grew equally well after transplantation to either normal or thymectomized recipients[4] In the terminology used for describing carcinogenesis in endocrine tissues, the state of the lymphoid cells in 6-week-old *AKR* mice could be described as being 'thymus dependent', while fully developed leukæmic cells could be regarded as being in a 'thymus autonomous' state The experiments reported here were undertaken to investigate the state of the lymphoid cells in apparently normal 6-month-old *AKR* mice—that is, in mice late in the pre-leukæmic period

Seven-week-old male ($AKR \times C3H)F_1$ hybrid mice (incidence of spontaneous leukæmia 50 per cent at 1 year) were submitted to either thymectomy or sham thymectomy The following day, pools of spleens were collected from histologically normal 6-months-old male *AKR* mice (3 spleens per pool) These spleens were minced and prepared as cotton-filtered single-cell suspensions in tissue culture 199 medium Each F_1 hybrid mouse was injected intravenously with 10–20 × 10^6 spleen cells in 0 1 ml fluid Approximately equal numbers of thymectomized and sham-operated mice received cells from each spleen pool The mice were observed for the development of leukæmia When moribund, the mice were killed and tissue from each leukæmic animal was transplanted intramuscularly to four 6-week-old male recipients of the following strains *AKR*, *C3H* and ($AKR \times C3H$) F_1, to determine the genotype of the leukæmic cells

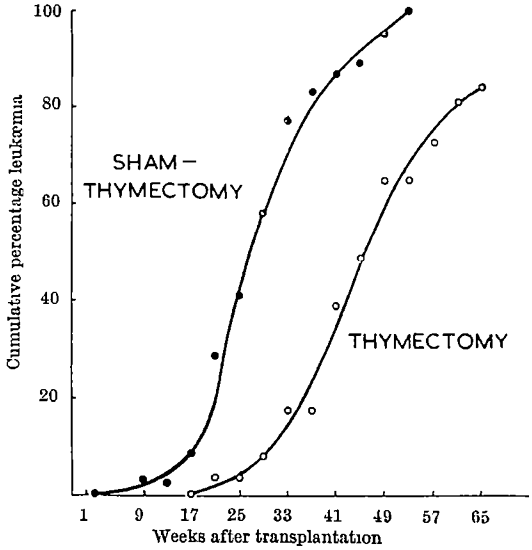

Fig 1 Cumulative development of advanced lymphoid leukæmia in thymectomized and sham-operated ($AKR \times C3H)F_1$ hybrid mice injected intravenously at the age of seven weeks with six-month-old *AKR* spleen cells

Fig 1 shows the cumulative development of advanced leukæmia in 23 thymectomized and 31 sham-operated F_1 hybrid mice injected with the *AKR* spleen cells Leukæmia occurred in all 31 sham-operated mice and appeared earlier than in the thymectomized mice In the sham-operated recipients, the leukæmias were lymphoid in type, and took the form of a thymic lymphoma with, or without, spread to other organs In the thymectomized recipients 20 of the 23 mice developed lymphoid leukæmia, the disease involving the lymph nodes, liver, spleen and kidneys An additional thymectomized mouse, aged 66 weeks developed an atypical reticulum cell sarcoma Transplantation of these lymphoid leukæmias revealed the following distribution of genotypes *Leukæmias in sham-operated mice* , No tested 29/31 No of *AKR* type 17 No of ($AKR \times C3H)F_1$ type 12 *Leukæmias in thymectomized mice*, No tested 18/20 No of *AKR* type 16 No of ($AKR \times C3H)F_1$ type 1 (One lymphoid leukæmia in the thymectomized group failed to grow on transplantation)

Considering only those lymphoid leukæmias shown to have originated from the injected *AKR* cells, the mean latent interval between injection and the development of advanced leukæmia was 29 weeks for the sham-operated mice, and 43 weeks for the thymectomized mice

On intramuscular transplantation to test *AKR* mice, the 16 *AKR* leukæmias arising in thymectomized hosts killed the recipient mice as rapidly (mean latent period to death eight weeks) as did the 17 *AKR* leukæmias arising in sham-operated mice (mean latent period to death seven and a half weeks)

The results indicate that the splenic lymphoid cells from the preleukæmic 6-month-old *AKR* mice did not need the presence of the thymus to progress to frank neoplasia However, they became neoplastic more rapidly if the thymus was present Supporting this conclusion was the observation that the *AKR* leukæmias arising in the sham-operated F_1 recipients appeared to originate in the thymus On transplantation, no difference was observed between the growth-rates of *AKR* leukæmic cells having originated in thymectomized mice and those arising in sham-operated mice

The results suggest that in *AKR* mice late in the preleukæmic period, the lymphoid cells are in a thymus-responsive state, and that in the development of leukæmia in *AKR* mice, the lymphocyte–thymus interrelationships fit the pattern of progressive stages previously demonstrated in the genesis of endocrine tumours (dependency to responsiveness to autonomy) The present results do not provide information on the problem of whether or not thymus-responsive lymphoid cells are, in reality, neoplastic cells It may be argued that there are dormant leukæmic cells present in *AKR* mice late in the preleukæmic period If this is the case, the present evidence would then suggest that the emergence from such a dormant state is stimulated by but not dependent on, the presence of the thymus

Successful Dissection of the Salivary Glands of *Anopheles* Mosquitoes Three Months after Storage at –70° C.

It has been demonstrated that the sporozoites of several species of plasmodia remain viable for several years when stored at temperatures around – 70° C [1]

The technique usually adopted is to dissect the salivary glands and, after confirming the presence of sporozoites, to store them in serum or plasma obtained from the susceptible host, that is, *P vivax* and *P falciparum* in human serum, *P cynomolgi* in rhesus serum, etc To be able to preserve malarial sporozoites for indefinite periods outside the intermediate host is of great value to research workers, but the technique of dissecting the salivary glands following the rupturing of mature oocysts must be carried out before the glands become depleted as the result of repeated feedings by the mosquito, and also the technique of dissecting is time-consuming

With these criticisms in mind it occurred to us to investigate whether the internal tissue of mosquitoes could be dissected after they had been stored for some time at low temperatures We have now demonstrated that both the salivary glands and the mid-guts of mosquitoes stored dry in sealed test-tubes for three months at – 70° C can be dissected as easily as in freshly killed mosquitoes.

Our usual routine technique for dissecting the salivary glands was used[2] The dissections were carried out 3 hr after the mosquitoes had been removed from the deep-freeze chamber

We propose shortly to repeat this experiment, using infected mosquitoes and after storing for several months, to dissect the glands to test the viability of the sporozoites by injecting them intravenously into a susceptible host It may be worthy of mention here that during the practice of malaria therapy over the past 38 years, we have injected by intravenous injection of sporozoites from dissected salivary glands about a thousand patients and that we have never had a failure[3]

Enzyme Leakage, Antihistamine Drugs and Adrenalectomy in Renal Tubular Necrosis

THE release into the circulation of cellular respiratory enzymes, notably iso-citric and glutamic dehydrogenase, as a result of experimental hepatic necrosis is well documented[1], and the phenomenon has provided a useful means of following the course of such necrosis and of demonstrating the prevention of damage to liver by drugs such as 'Phenergan' (promethazine hydrochloride) and by prior adrenalectomy[2,3]

The investigation reported here represents an attempt to demonstrate similar leakage of enzymes following necrosis of renal tubules produced by heavy metals and to prevent such damage by prior adrenalectomy and by administration of drugs that protect animals against toxic liver necrosis The excretion of lactic dehydrogenase in patients suffering from a variety of renal disorders has already been demonstrated[4]

Kidney damage was produced in male rats of the albino Wistar strain and weighing 150–200 gm by a single intraperitoneal injection of uranyl nitrate (6 mgm /kgm of the salt) This dose caused widespread necrosis of the proximal convoluted tubule[5], demonstrable at 24 hr and maximal at 48 hr after injection Anti-histamine drugs were given by subcutaneous injection 15 min before administration of uranyl nitrate in a dosage of 25 mgm /kgm , repeat injections (12 5 mgm /kgm) being given 6 hr and 24 hr later Bilateral adrenalectomy was performed on 12 rats 12 days before injection of uranyl nitrate, the animals being maintained on 1 per cent sodium chloride in place of drinking water Urine was obtained by placing the rats in a metabolic cage and collecting the urine 2–3 hr later, and iso-citric dehydrogenase activity determined on 0 4 ml samples by the previously published method[1] Samples were stored at – 10° until required

Kidney sections were obtained by killing animals at 15, 24, 48, 72, 96 and 168 hr after injection of uranyl nitrate The material was fixed in neutral buffered formol-saline and the sections stained with hæmatoxylin–eosin

Following the injection of uranyl nitrate, there was at no time a detectable rise in the level of iso-citric dehydrogenase in 1 ml samples of serum However, as can be seen in Table 1, significant amounts of this

Table 1 RENAL TUBULAR NECROSIS AND THE EXCRETION OF ISOCITRIC DEHYDROGENASE AFTER INJECTION OF URANYL NITRATE

Time after injection of uranyl nitrate (hr)	Isocitric dehydrogenase in urine (μmol TPN reduced/hr /ml)	Isocitric dehydrogenase in serum	Renal tubular necrosis
15	0 60	Nil	Nil
24	0 95	Nil	Early
48	1 50	Nil	Severe
72	0 60	Nil	Severe
96	Nil	Nil	Severe
168	Nil	Nil	Severe

enzyme appeared in the urine, the quantity being highest at 48 hr and none being detectable at 96 hr Thus tubular necrosis and enzyme leakage reached their maximal development at about the same time

The presence of enzymes in the urine but not in the blood seems best explained by some kind of preferential excretion from the damaged tubular epithelium into the urinary outflow Origin from urinary cellular sediment was excluded by examining this sediment Recognizable cells or cell nuclei were very scanty, and no differences were observed between samples taken at 48 and at 96 hr Again, the degree of bacterial contamination was similar at both these times

The administration of a number of anti-histamine drugs and also prior adrenalectomy were used in attempts to prevent renal tubular necrosis after injection of uranyl nitrate The drugs used were 'Phenergan' (promethazine hydrochloride), 'Sparine' (promazine hydrochloride) 'Anthisan' (mepyramine maleate) and methdilazine hydrochloride, each compound being given to 6–12 rats In no case was tubular epithelial necrosis lessened, nor was the excretion of iso-citric dehydrogenase diminished The failure of these measures, in contrast to their efficacy in liver damage due to organic poisons[2,3] or viruses[6], may be attributable to the irreversible nature of the toxic effects of heavy metals

Distribution as a Determinant of Iron Hepatotoxicity

EXAMINATION of clinical material of an appropriate nature indicates not only that iron is hepatotoxic, but suggests the definition of the conditions under which this is so The most critical of these appears to be the parenchymal accumulation of iron to a level at which liver cell death is effected[1] An attempt to verify this concept in laboratory animals has resulted in an affirmation of this point of view

Mice 8 weeks old of the Great Ormond Street strain were injected with iron–dextran ('Imferon') in divided doses to a total of 1,000 mgm /kgm At the end of 3 weeks, approximately 1 week following the final injection of iron–dextran, a group of control and a group of injected animals were killed by cervical dislocation Slices of liver were fixed in buffered 10 per cent formalin and stained with hæmatoxylin and eosin and Perl's reaction for iron Other slices were frozen and examined histochemically and chemically for glucose-6-phosphatase by the techniques of Chiquoine[2] and Swanson[3] respectively This was repeated at the end of 5 months with animals from the same groups, maintained on the routine laboratory chow

A marked difference was present in the hepatic distribution of iron in the two groups of animals In the animals killed shortly after termination of the injections, stainable iron was predominantly located in reticuloendothelial elements In animals killed after relatively long-term survival, much larger quantities of stainable iron were found in the parenchymal cells, with correspondingly less in the reticuloendothelial elements These observations were similar to those originally made by Golberg[4]

Histochemically, glucose-6-phosphatase is markedly diminished in all iron-loaded livers, a finding which will be discussed in detail elsewhere[5] This reduction was more marked in those animals killed 5 months after the last injection, with predominant parenchymal iron storage

Chemical values show a similar accentuation of loss of glucose-6-phosphatase in the long-term iron-loaded animals as opposed to the short-term animals (Fig 1) Age *per se* did not appear to cause a decrease in glucose-6-phosphatase values in control animals

Glucose-6-phosphatase in the liver can be shown to be consistently reduced as a response to hepatic iron loading[5,6] The results of this experiment demonstrate that this response to iron accumulation is proportional to the intensity of parenchymal cellular iron accumulation This indicates that the intrahepatic distribution of storage iron is significant in

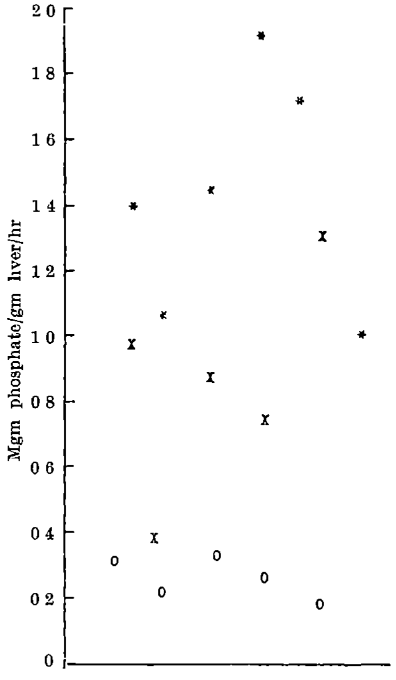

Fig 1 Effect of iron storage and distribution on hepatic glucose-6-phosphatase levels Short-term animals have predominantly reticuloendothelial storage, long-term animals predominantly parenchymal storage *, Controls, ×, short term, O, long term

these terms The reduction of glucose-6-phosphatase does not necessarily reflect a necrogenic property of storage iron, but this property can be inferred from other studies[1,7], and it seems reasonable to expect that if one intracellular biochemical effect parallels the intensity of specifically parenchymal iron stores, others will do likewise These results are thus compatible with the theory of the pathogenesis of certain types of iron storage disease previously proposed[1]

BIOLOGY

Protein Synthesis in Chloroplasts during Photosynthesis

SINCE isolated chloroplasts incorporate radioactive amino-acids into their proteins[1-3], it is widely assumed that chloroplasts can synthesize their own protein moieties There is, however, little evidence available to show whether chloroplasts do, in fact, play an active part in the synthesis of proteins in the living leaf cell[4]

I have investigated the incorporation of radioactive products into chloroplast protein after supplying illuminated chloroplasts, isolated from leaves of *Spinacia oleracea*, with $^{14}CO_2$ in the presence of tissue extract containing endogenous amino-acids (for methods see refs 5–7) Among the soluble components formed from $^{14}CO_2$ were alanine and aspartic acid, which were incorporated into chloroplast protein at a rate of 0 1–0 5 per cent of the respective protein-bound amino-acid per hour The incorporation into insoluble protein, sedimentable at 20,000*g*, was up to 10 times higher than that into the soluble supernatant protein The incorporation reaction differed from that usually observed with ribosomes in that ribonuclease and chloramphenicol, even at high concentrations, were not inhibitory Omission of other amino-acids in the reaction mixture did not appreciably decrease the rate of incorporation of ^{14}C-aspartic acid These results may indicate different mechanisms of incorporation of amino-acids into proteins in ribosomes and chloroplasts In view of the low rates of incorporation, however, it cannot be ruled out at present that the reaction in chloroplasts is an artefact spinach chloroplasts contain 15–40 per cent of the total amino-acid activating enzymes of the cell (determined with chloroplasts isolated in an organic solvent after freeze-drying of the leaves (cf refs 8–10) From the observations of Karasek *et al* [11] it can be concluded that an equilibrium exists between the activated amino-acyl adenylate enzyme complex and the free amino-acyl adenylate The latter, however, is known to react unspecifically with protein forming peptide bonds[12,13] This unspecific reaction could possibly explain the low rates of incorporation of amino-acid into the protein of isolated chloroplasts, although it remains uncertain, in that case, why amino-acids are incorporated preferentially into the insoluble protein

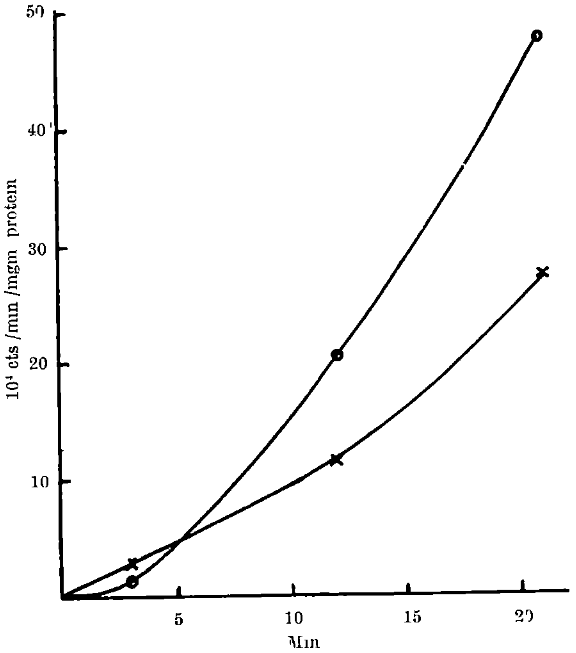

Fig 1 Time-course of incorporation of carbon-14 into soluble proteins of chloroplasts and cytoplasm during photosynthesis of intact leaves in the presence of $^{14}CO_2$ ×, Specific activity of soluble chloroplast proteins, O, specific activity of soluble cytoplasmic proteins

Thus, *in vitro* studies give no clear-cut evidence as to whether, and, if so, to what extent, protein synthesis actually occurs within the chloroplasts Such evidence is obtained from studies *in vivo* After 4-min exposure in the dark to $^{14}CO_2$, mature spinach leaves were illuminated for a certain period of time, then immersed in a petroleum ether/dry ice mixture at about − 80° C, and afterwards freeze dried From the frozen dried material chloroplasts and residue were isolated in petroleum ether/carbon tetrachloride mixtures[14] The specific activities of soluble and insoluble proteins of chloroplasts and residue were determined From these and additional data on the protein distribution within the cell the specific activities of cytoplasmic proteins could be calculated[9,10] Fig 1 shows results of a kinetic experiment In chloroplasts radioactive compounds are incorporated into soluble protein as soon as photosynthesis is initiated Contrary to this, the incorporation of radioactivity into soluble cytoplasmic proteins shows a lag period of at least 2 min It can be inferred that this delay is caused by a lack of radioactive precursors of protein formation which have to diffuse from the chloroplast to the cytoplasm From the earlier appearance of radioactivity in chloroplast proteins than in cytoplasmic proteins it is concluded that protein synthesis actually takes place within the chloroplast, and that photosynthetic products are directly incorporated into protein In chloroplastic as well as in cytoplasmic proteins, especially alanine, aspartic acid, glycine and serine become labelled during the first minutes of photosynthesis The appearance of radioactivity in the amino-acids of hydrolysed chloroplastic protein after 12-min photosynthesis and the intensity of ninhydrin staining of the same amino-acids can be compared qualitatively from Figs 2 and 3

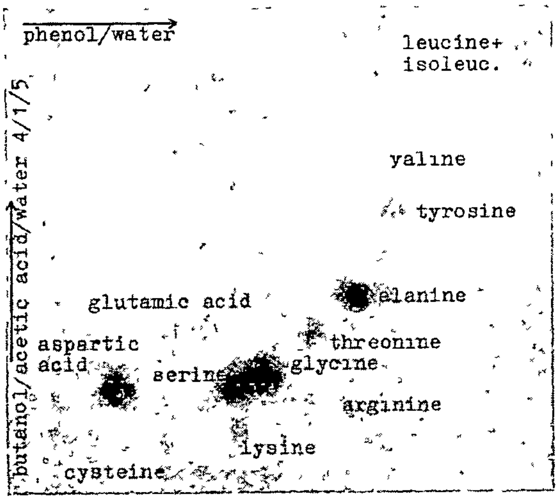

Fig 2 Radioautogram of amino-acids of hydrolysed chloroplast protein, separated by two-dimensional paper chromatography, after 12 min photosynthesis of intact leaves in the presence of $^{14}CO_2$

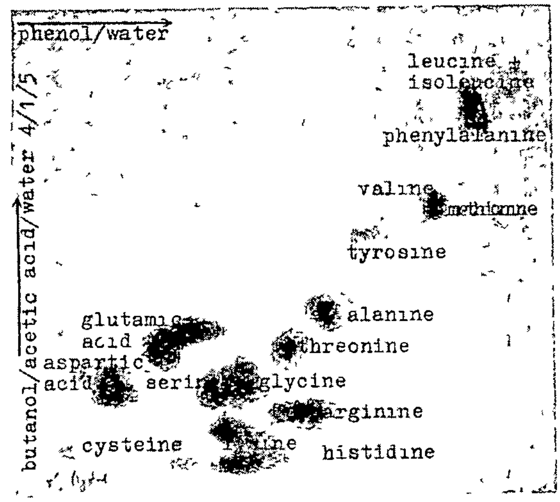

Fig 3 Same amino-acids as in Fig 2, chromatogram stained with ninhydrin

The time-curves of the specific activities of insoluble proteins of chloroplasts and cytoplasm essentially resemble those of the soluble proteins shown in Fig 1, but rates of incorporation are higher. Maximum incorporation-rates observed are about 1–1·3 μgm and 1·9–2·4 μgm amino-acids per mgm. protein in an hour in soluble and insoluble chloroplast proteins respectively. This compares with 1·7–2·2 μgm amino-acids in soluble and 2·4–3 μgm in insoluble cytoplasmic proteins. These values are calculated from the specific activity of the added $^{14}CO_2$ assuming the same specific activity in the carbon of the amino-acids formed therefrom. It must be kept in mind, however, that pools of amino-acids most probably are not saturated with ^{14}C in these short-time experiments. Therefore actual protein synthesis is almost certainly considerably higher than indicated by the foregoing values.

In any event, protein synthesis by chloroplasts contributes considerably to the total protein synthesis of the leaf cell.

This investigation was supported by a grant from the Deutsche Forschungsgemeinschaft.

Spore Dispersal in *Pyricularia grisea* (Cooke) Sacc.

Pyricularia grisea is probably best known in relation to 'blast' disease of rice. Some workers have considered this fungus to be the causal organism, but others ascribe the disease to a distinct species *P. oryzae* Cav.[1]. *P. grisea* is associated with 'pitting' disease of Cavendish bananas in Brazil, Trinidad and Australia[2–6]. Pitting is commonest on the finger-stalks and cushions of the large proximal hand of the bunch and, in advanced stages, may result in finger-dropping. Groups of spots or pits may also be scattered over the fruit surface. In attempting to explain the distribution of pits on the bunch, Wardlaw[4] suggested that *P. grisea* "may be widely and abundantly disseminated by wind", however, this was not investigated further. No conidia of *P. grisea* were detected during an earlier survey of the air-spora of Jamaican banana plantations[7], but in recent aerobiological studies appreciable spore counts were recorded and these are the subject of the present communication.

A Hirst spore trap[8] was operated in a banana plantation near Old Harbour from November 1, 1961, until January 26, 1962. Methods of operating the trap and estimating atmospheric spore concentration (expressed here as number of spores per cubic metre of air) were those of Hirst[8,9]. No corrections for variation in trapping efficiency were made so that all spore concentrations quoted are under-estimates[9]. Conidia of *P. grisea* trapped on the slides were obclavate, tapered at the apex, truncate or extended into a short projection at the base, 2-septate, almost hyaline and measured 20–35 × 10–13μ.

The mean diurnal periodicity curve (Fig 1) was derived from the arithmetic means of the estimated numbers of conidia at each even hour, plotted according to Hirst[9]. Rapid conidium liberation started at about midnight and was at a peak near 04.00 hr. E.S.T., low concentrations occurred during daylight. The period of most rapid liberation corresponded with the time when humidity was maximal. The highest 2 hr. estimate recorded was about 530 conidia per m^3 at 04.00 hr. on December 5.

Daily mean conidium concentration was estimated by averaging the 2 hr. counts for the period

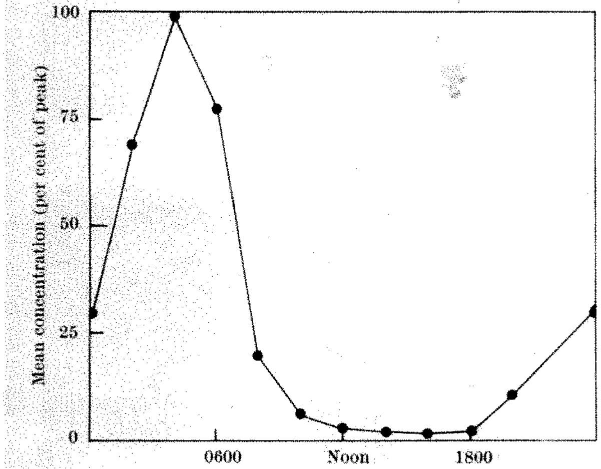

Fig. 1. Mean diurnal periodicity curve for conidia of *Pyricularia grisea* in the air of a Jamaican banana plantation

24.00–24.00 hr. each day. Values are related to total daily rainfall in Fig. 2. In dry spells, concentration rarely exceeded 30 conidia per m.^{3} and on a total of 17 days no conidia were trapped. Rainfall was usually followed by an increased concentration on the following night, the highest value recorded being 136 conidia per m.^{3} on December 5 after 0·24 in. rain during the previous afternoon. Increased concentrations sometimes occurred when there had been no previous rain but when night-time humidity was exceptionally high, for example, during the first half of November.

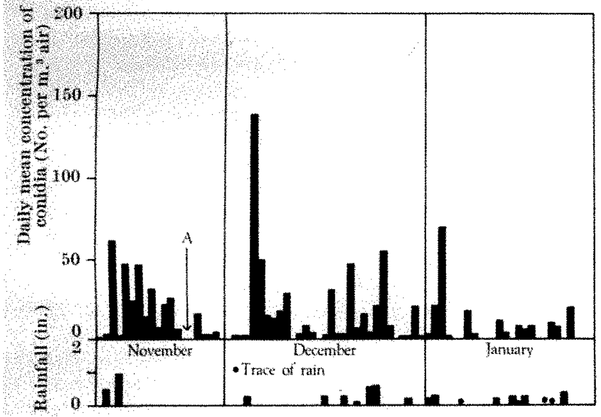

Fig. 2. Daily mean concentration of *Pyricularia grisea* conidia related to rainfall during period November 1, 1961–January 26, 1962. Arrow (*A*) indicates period when trap was out of order (November 14–25)

Colonies of *P. grisea* were found on decaying transition leaves, flower bracts and, more rarely, on old leaf spots caused by *Deightoniella torulosa*, *Cordana musae* or both. However, the fungus appeared to be less common than in Trinidad or Brazil where, according to Wardlaw[4], conidia are formed in great abundance on the Cavendish variety. Laboratory tests showed that high humidity (> 95 per cent relative humidity) was necessary for sporulation, this being at a peak when the spore-bearing substratum was wet. This helps to explain the increased atmospheric spore concentrations following rainfall and, also, the fact that pitting disease is most severe during rainy periods[4].

These findings confirm Wardlaw's[4] suggestion that *P. grisea* conidia are air-borne, although in the plantation sampled conidia of this fungus were rather uncommon and accounted for less than 0·1 per cent of the total air-spora. Periodicity is similar to that in many ascomycetes and basidiomycetes but contrasts with that in several other hyphomycetes, for example, *Deightoniella torulosa*, *Cordana musae* and *Curvularia* spp., which are maximal when vapour pressure rapidly decreases (07.00–09.00 hr.)[7,10,11]. Regular periodicity may be due to the operation of an active discharge mechanism under humid conditions, but this has not been investigated.

A Particulate Inoculum for Non-Sporing Fungi

DURING investigations into the soil ecology of *Rhizoctonia repens* Bernard, a non-sporing mycorrhizal fungus of certain orchids, it became necessary to effect a uniform distribution of the fungus throughout the non-sterile experimental soil.

Ludwig, Clark, Julien and Robinson[1] have investigated the suitability of various inocula for the production of a uniform soil infestation and they concluded that a sand–cornmeal inoculum was the best. They attributed its suitability to: (1) the adequate nutrient base; (2) the small particle size of the inoculum, allowing very uniform distribution.

In the case of *R. repens*, sand–cornmeal was tried and found to have two serious defects. First, several additions of water were needed to maintain a suitable moisture content during the long period required for the slow-growing fungus to become thoroughly established in this medium. Secondly, regardless of how long the fungus remained growing in it, residual nutrients supported a prolific growth of 'sugar' fungi when the inoculum was introduced into soil.

These two problems were largely overcome by using exfoliated vermiculite moistened with various nutrient solutions to grow the fungus, then leaching out residual nutrients with several washings of sterile distilled water.

The flakey particles produced by heating micaceous vermiculite crystals in the vicinity of 2,000° F. are capable of taking up large quantities of water, but providing the individual particles are sufficiently large a continuous system of air spaces remains between them at field capacity. From the range of sizes available for building and horticultural purposes, a grade passing A.S. sieves between − 10 and + 18 was selected for the above use. 100 c.c. of this were placed in a 250 ml. conical flask and moistened to approximately field capacity with 35 ml. of potato-dextrose or a synthetic nutrient solution. This was autoclaved and inoculated with the fungus. After 6–8 weeks incubation at 25° C. the contents of the flask were flooded 6 times with 150 ml. lots of sterile distilled water, shaken and decanted. This removed the bulk of the nutrients and separated the vermiculite particles ready for use. The fungal hyphæ were not significantly dislodged from between the crystal lamellæ and remained fully viable.

This medium can be easily varied to satisfy the requirements of other fungi by altering the particle size and nutrient composition and it may perhaps be successfully applied to other experimental situations requiring a discrete hyphal inoculum having negligible nutrient status.

Limitations still inherent in the technique include the fact that vermiculite introduced into soil brings about physical and inorganic chemical changes there. The relatively high cation exchange capacity of the vermiculite gives rise to the latter effect and this same property will also produce changes in the composition of nutrient solutions used to grow the fungus. An alteration in *p*H can result and it may be an advantage to use vermiculite from the Nat Kruit deposit in South Africa, which is unique in possessing a natural *p*H slightly below neutrality.

This work was carried out during the tenure of a Commonwealth Scientific and Industrial Research Organization postgraduate studentship.

Cobalt and the Fixation of Nitrogen by Root Nodules of *Alnus* and *Casuarina*

THE recent discovery that cobalt is essential for nitrogen fixation in leguminous root nodules[1–5] suggested that there might be a similar requirement for that element in the fixation proceeding in the root nodules of several non-leguminous genera[6] for which molybdenum has recently been shown to be needed[7,8].

Experiments have been carried out with *Alnus glutinosa* and *Casuarina cunninghamiana* using sand and water-culture methods already described[7–9]. The major nutrient reagents were purified by co-precipitation of cobalt with 8-hydroxyquinoline in the presence of iron and aluminium[4,9] followed by co-precipitation with ferrous sulphide at *p*H 8 (ref. 10) and finally by autoclaving the solution in the presence of magnesium hydroxide and calcium phosphate at *p*H 10 (refs. 9 and 11). The cobalt content of the nutrient solutions due to residual contamination of the purified reagents was estimated to be approximately 0·00002 p.p.m.

Alnus seed was sown in purified sand in late May, 1960, the seedlings being transplanted into water culture, then inoculated as previously described[8] and given either 0·01 p.p.m. or no extra cobalt. No combined nitrogen was supplied, apart from an initial addition of 0·8 mgm. ammonium-nitrogen per plant to sustain the plants over the period of nodule formation. Comparable experiments in sand-culture were begun in mid-July 1960. At the end of the rather short first growth season permitted by these starting dates, there were no clear visible differences between treatments, though a harvest of a proportion of the water-culture plants showed a slight superiority in dry weight and nitrogen content on the part of the plants given cobalt.

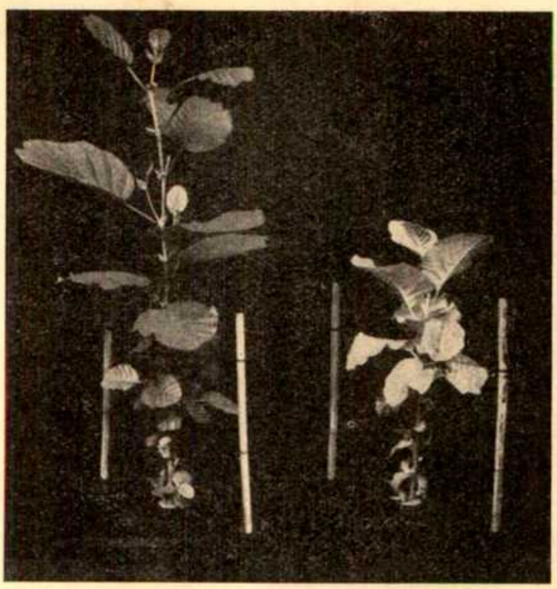

Fig. 1. Nodulated plants of *Alnus* grown in water culture with (left) and without (right) cobalt supplied, photographed by Mr. R. Cowper in late May 1961 (× *c.* ¼)

Plants were retained in the cultures for further observation. In spring, 1961, the sand-culture plants given cobalt emerged from winter dormancy about two weeks before those grown without cobalt, and visible differences in vigour and leaf colour were apparent by mid-June. Differences between treatments were, however, more marked in the water-culture plants, and by mid-May the plants grown without cobalt showed signs of nitrogen deficiency which became progressively more severe as time passed (Fig. 1). Results obtained at the harvest, in late June 1961, of the seven plants in each treatment are given in Table 1 and show a clear effect of cobalt on height, dry weight, percentage nitrogen (especially foliar), and nitrogen fixed. Calculation indicates that when cobalt was provided, 306 mgm. nitrogen was fixed per gm. of nodule dry matter formed, the corresponding figure without cobalt being 131. The addition of cobalt to a deficient plant resulted in a gradual disappearance of symptoms of nitrogen deficiency, complete in two months. Spectrographic analyses for dry material showed that plants given cobalt contained 0·39, 14, 3·7 p.p.m. cobalt in tops, roots and nodules respectively, while those given no cobalt contained 0·11, 0·05 and 0·09 p.p.m. in the same parts.

Casuarina plants similarly developed acute chlorosis characteristic of nitrogen deficiency when grown without cobalt. The results described here clearly

Table 1. EFFECT OF COBALT SUPPLY ON GROWTH AND NITROGEN FIXATION BY *Alnus glutinosa*

Treatment	Mean height of shoot (cm.)	Mean dry weight per per whole plant (gm.)	Mean nodule dry weight per plant (gm.)	Mean percentage nitrogen in leaf dry matter	Mean percentage nitrogen in whole plant dry matter	Mean total nitrogen per plant mgm. *
+ Co	34·4	8·60	0·453	2·34	1·62	139·0

Isolation of Thermophilic Actinomycetes

To judge from reports in the literature, thermophilic Actinomycetes have proved difficult to isolate. For isolations from mouldy hay we have developed a convenient method which promises to be useful in other contexts[1]. The method uses the fact that dry air removes spores of the Streptomycetaceae in preference to bacteria. Instead of suspending the spores in water and plating dilutions in the traditional manner, dry spores are suspended in air and impacted with the Andersen sampler[2] directly on surface-dried medium. In our work, samples of hay are shaken in a small wind tunnel and the air drawn into an Andersen sampler loaded with Petri dishes which had been poured the day before with half-strength nutrient agar (agar content made up to 2 per cent) containing 0·5 mgm./ml. actidione to suppress growth of mould. A slit-sampler could be used as an alternative to the Andersen sampler, and instead of using a wind tunnel, hay or other material can be shaken in a box (pre-sterilized with propylene oxide if required) and a few minutes allowed for larger particles to settle before sampling the air.

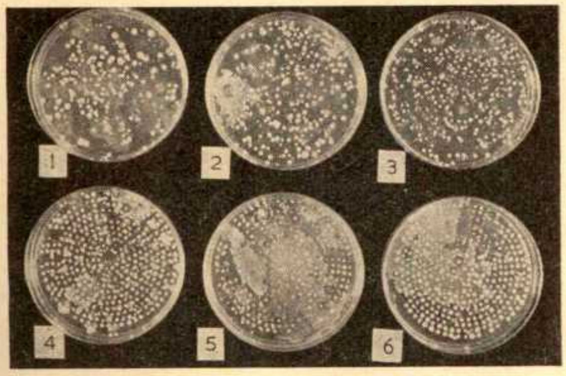

Fig. 1. Petri dishes from stages 1–6 of Andersen sampler exposed to dust from mouldy hay (associated with farmer's lung) for 5 sec. in wind of 4·2 m./sec., incubated at 60° C. for 42 hr. Note antibiotic produced by some colonies of Actinomycetes

After exposure in the Andersen sampler the plates are incubated at either 40° or 60° C. At 60° white sporing colonies develop overnight (Fig. 1), and at 40° many different forms develop more slowly. At either temperature many slow-growing colonies develop on prolonged incubation. During the past two years many thousands of colonies growing at 60° C. have been obtained in culture by this method from hay associated with cases of farmer's lung.

Collateral Biliary Channels

Following ligation of the common bile duct in the rat normal biliary drainage is restored within 7–12 days after operation.

Investigations previously carried out by Trams and Symeonidis[1] described "recanalization" of the common bile duct occurring 14 days after the occlusion. They suggested that it was brought about as follows: (1) Dilation of the duct above the site of ligation producing a distended sac. (2) Prolapse of the walls of the sac around the ligation. (3) Adherence between the walls of the distal part of the bile duct and the prolapsed walls of the sac. (4) Necrosis of the adherent walls restoring the continuity of the common bile duct.

Our results based on a series of animals killed at intervals ranging between 24 hr. and 3 weeks after operation disproved the mechanisms of recanalization suggested by Trams and Symeonidis[1]. They show conclusively that normal drainage of bile is brought about by the outgrowth of new channels from pre-existing biliary epithelium. These arise from the bile duct immediately distal to the ligation, encircle the ligature and join up with the distended proximal sac (Fig. 1). This process is initiated immediately after ligation and is complete at 7–12 days after operation.

The findings have been confirmed by (*a*) radiological and (*b*) histological observation. The radiological approach was similar to that described previously for the spleen by Braithwaite and Adams[2]. It consisted of injecting a radiopaque medium ('Micropaque', Damancy and Co.) either into the bile duct proximal to the site of ligature (that is, the dilated sac) or alternatively into the bile duct immediately distal to the ligature. This was carried out at varying time-intervals after operation and the passage of medium was observed directly using cineradiography—radiographs were taken at intervals during the course of injection for later examination.

At periods from 7 days after operation the medium passes through the newly formed channels into the distended sac when retrograde injection is performed. When the injection is carried out above the ligation the channels are more difficult to demonstrate.

The outgrowths demonstrated radiologically have been confirmed by histological observation of serial sections of the biliary tract immediately below the

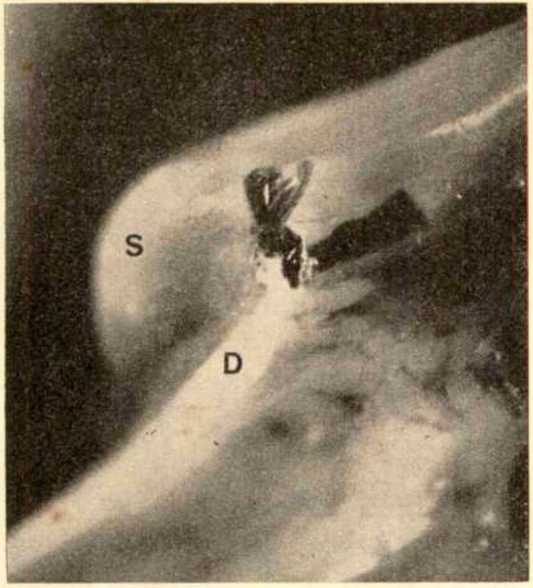

Fig. 1. Collateral biliary outgrowths encircling site of ligation. Specimen injected with 'Micropaque' 7 days after ligation. *D*, Bile duct; *S*, sac. (× 2·7)

site of ligation. Mitotic figures can be clearly seen in material stained with Heidenhain's iron hæmatoxylin.

A comparable series of animals in which the bile duct draining a single liver lobe was ligated shows different results.

Contrary to the views expressed by Kraus and Beltran[3], who postulated that changes occurred similar to those described by Trams and Symeonidis[1] after ligation of the common bile duct, present findings show that their interpretation is incorrect.

Following ligation of the lobar bile duct draining the central lobe of the rat liver, restoration of drainage is brought about by the enlargement of pre-formed biliary canaliculi which course along the walls of the lobar portal veins and their tributaries (Fig. 2). These channels begin to enlarge after operation and form a plexiform system of collateral vessels which is well established after a week. This arrangement is present in similar form at 3 weeks after operation.

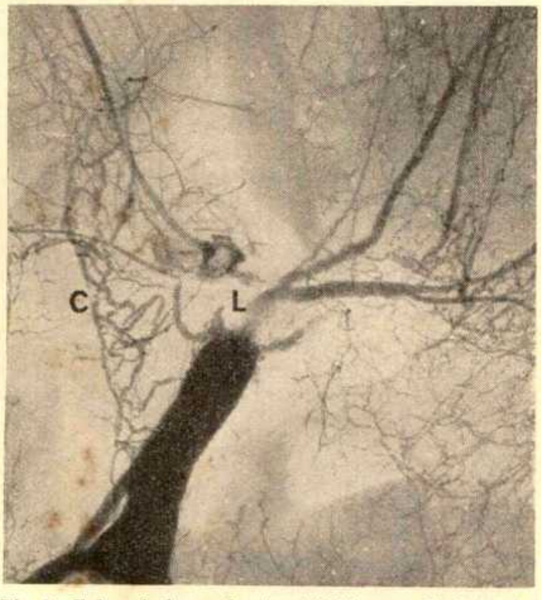

Fig. 2. Enlarged plexus of periportal biliary canaliculi injected with 'Micropaque' 7 days after ligation of central lobar duct. Note site of ligation and course of collateral vessels on wall of portal vein which they outline. *L*, Ligation site; *C*, biliary canaliculi. (× 6)

Periportal biliary canaliculi do not contribute to the collateral drainage when the common bile duct is ligated, since at this site the portal vein on which the biliary canaliculi run is not in close proximity.

The importance of these collateral biliary pathways will be described in detail elsewhere.

A Bivalved Gastropod from the Hawaiian Islands

A SINGLE specimen of a bivalved gastropod (opisthobranchs first described by Kawaguti and Baba[1]) was recently collected alive at Koloa, Kauai, Hawaii. This apparently represents the first living specimen of a species of the sub-family Berthelininae to be described from a Pacific Island.

The specimen was on a sample of *Caulerpa racemosa* var. *turbinata* (J. Ag.) Eubank which was growing around a basalt boulder at the low tide-level. When extended the animal is approximately 6 mm. in length and 4 mm. in diameter. The animal and its shells (Fig. 1) resemble the alga both in form and colour. The convex dorsally carried shells are similar in shape to the inflated fronds of the alga. The body colour is bright emerald green, ornamented with opaque milk-white spots on the oral tentacles and the rhinophores. The head and neck of the animal are microscopically speckled with brown and the dorsal surface of the foot with white. The shell is distinguished from the general body colour by fine radiating lines of red-brown from the mantle, and the adductor muscle shows through as a circular yellow spot on each valve.

The shells are 4·3 mm. in length, 3 mm. in height, and 1·3 mm. in diameter. The valves are smooth, thin, and translucent. The sculpture consists of fine concentric growth lines. The nucleus is on the left valve only, consisting of a translucent white area of 1½ whorls which overlie the dorsum of the valve so that it is on a nearly horizontal plane with the hinge line. It does not extend over the right valve.

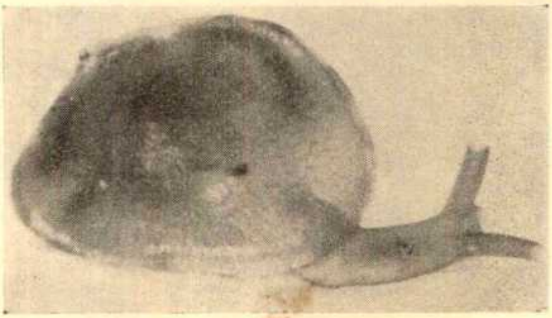

Fig. 1. Living animal of *Berthelinia* sp. from the right side

The specimen has been compared with preserved specimens of *Berthelinia limax*[1] from Japan, *B. typica* (Gatliff and Gabriel) from Australia[2], and *Midorigai australis* Burn[2] from Australia. In the Hawaiian specimen, the shells are shorter from anterior to posterior in relation to height of the valve than are the shells of *B. limax*, and they differ from both *B. typica* and *M. australis* in the blunt, rounded anterior and posterior ends. The nucleus of the Hawaiian specimen differs from those of *B. limax* and *B. typica* in that it is closely applied to the dorsum rather than being elevated and erect; and it differs from that of *M. australis* in that it is smaller in relation to the size of the valve and does not extend over the right valve.

Designation of a specific name will await the collection of additional material.

Secretions of the Labral and Trunk Limb Glands in the Cladoceran *Eurycercus lamellatus*

THERE has been much dispute concerning the function of the labral glands of the Branchiopoda. Although Cannon[1-6] has long maintained that they produce a secretion which entangles particulate food prior to its being dealt with by the paired mouthparts, this has not been universally accepted. Among those who dispute this, Nicholson and Yonge[7] expressed the hope that new and independent evidence would be produced by others. Such evidence, which vindicates Cannon's belief, has been obtained from the chydorid cladoceran *Eurycercus lamellatus* (O. F. Müller), in which the labral gland secretions and their origin have been unequivocally demonstrated. Previous evidence was confined to the observation of secretions in the gland cell ducts[1] or, even in the much studied anostracan *Chirocephalus diaphanus* Prévost, to the demonstration of material adjacent to the labrum which was believed to have been produced by the labral glands[5,6]. In *Eurycercus*, secreted matter exuding from the ducts in the labrum has been clearly revealed (Fig. 1 *S*). This material is mixed with the food by special lobes on the first trunk limb (*L*) and by the maxillules.

The importance of entangling substances in the feeding mechanism is emphasized by the discovery of posteriorly originating secretions such as have not previously been reported in the Cladocera. In the Anostraca, secretions produced by superficial, segmentally arranged glands adjacent to the food groove and on the limbs have been described, and divergent views have been expressed regarding their possible function[4,5,8-10]. In *Eurycercus*, secretions are produced by large gland cells located near the base of the fourth trunk limbs. They are stored in voluminous reservoirs within these limbs (Fig. 2 *R*). An exit duct from each reservoir opens on the inner face of each limb. Discharged material (*PS*) is shown near the orifice of the exit ducts in Figs. 2 and 3. This is passed towards the food groove and forwards (Fig. 3 *A*), carrying with it particles filtered by the trunk limbs during the feeding process, an investigation of which is now nearing completion.

Expansion of the Foot in *Bullia* (Gastropoda)

Sandy-beach gastropods of the family Naticidae and of the genus *Bullia* (family Nassariidae) are capable of a remarkable expansion of the foot. So great is this expansion that it has often been suggested that the turgor of the foot is not due to hæmolymph alone but also to water from the surrounding medium which is supposedly introduced into the foot during expansion and expelled during contraction. Schiemenz[1,2] attempted to show such a mechanism in *Natica* and claimed to have demonstrated the existence of pores opening into an "aquiferous system" which was completely separate from the blood sinuses. Though these findings were accepted by a number of workers, including Gilchrist[3], they have never been corroborated, and most subsequent authors have assumed, as did Pelseneer[4], that the volume of hæmolymph is quite adequate for expansion of the foot in all gastropods. Nevertheless, a small body of opinion has tended to the view that in certain marine gastropods expansion of the foot may be brought about partly by the introduction of sea-water. Morris[5], working on *Uber*, has tried to resolve the controversy by measuring the volume of fluid given off when the animal retracts and comparing it with the volume of water contained in the "free space" and elsewhere when the animal is expanded. Her results are unfortunately inconclusive and her observation that the expelled fluid often contains "blood-corpuscles" adds a complication to the problem.

Bullia, being restricted to southern Africa, has received less attention than the Naticidae already mentioned. Gilchrist[3], in a paper which has been overlooked by subsequent authors, states that the foot of *Bullia digitalis* "is obviously too large for the shell, and it is at once seen that it has been filled in the expanded condition with a comparatively large quantity of water, as, on contraction . . . jets of water are squirted out, sometimes to a distance of several feet. In several cases the quantity of water discharged was found to be sufficient to fill the empty shell after removal of the animal. Sections of the foot showed that there were large spaces between the muscles of the foot, and there was also a slight involution of the epithelium at the openings". Clarke[6] is of the opinion that the expansion is brought about entirely by means of sea-water. In a more recent paper, one of us (A. C. B.)[7] has said that the foot of *Bullia* "is unlike the foot of most gastropods in that much of its interior is taken up by a cavity containing sea-water; this cavity communicates with the exterior by means of a duct opening below the operculum".

We are now in a position to state that the above information with regard to *Bullia* is incorrect. When the living snail retracts its foot, a thin jet of fluid issues with considerable force from what appears to be a pore situated in the mid-line between the posterior cirri; however, serial sections of the foot prove conclusively that no such pore exists. The sections also show that by far the largest space within the foot is the pedal sinus and that this is not in communication with the exterior at any point. The sinus, undoubtedly comprising Gilchrist's "large spaces between the muscles of the foot", contains hæmolymph in the living animal. It is not lined by any epithelium, some of the sections show the presence of hæmocytes, and fluid extracted from the cavity while the animal is alive reacts positively to tests for protein. We must therefore reject any suggestion that the mechanism of pedal expansion is basically different from that in other gastropods.

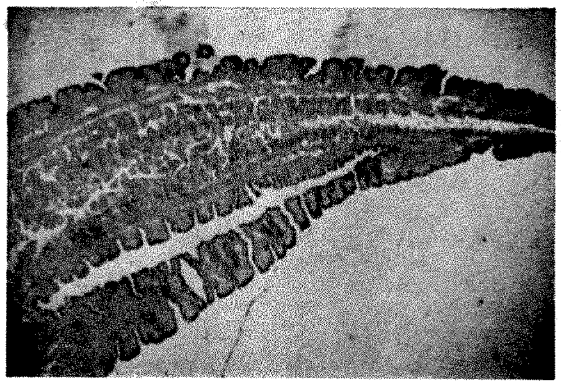

Fig. 1. Longitudinal section of posterior region of foot of *Bullia digitalis* showing 'aquiferous' space with channels to ventral surface. (× c. 30)

There are, however, spaces in the posterior region of the foot which are in direct communication with the exterior and must contain sea-water when the foot is expanded (Fig. 1). Such spaces have not been reported in other gastropods. They are a pair of blind sacs opening to the ventral surface by a series of channels, and it is apparent that they are, in fact, invaginations of the ventral epithelium. A pair of grooves is present on the ventral surface of the foot in this region and these are continued backwards, under the posterior cirri to the posterior margin of the foot. In life the common opening of these grooves gives the appearance of the pore already mentioned. It is apparent that during contraction of the foot water would be expelled from the "aquiferous spaces" and might issue from the posterior of the foot as a jet.

However, while this water may certainly contribute to the jet, it cannot possibly account for the volume of expelled fluid observed by Gilchrist[3] and measured by Brown[7]. The greater part of this volume must come from elsewhere, that is, from the "free space" between the shell and the living tissues, from the mantle cavity, or from the proboscis sheath. Water from these sources does not flow over the dorsal surface of the foot, as no grooves are present to conduct it and carmine particles sprinkled on to its dried surface are not disturbed as the animal retracts. On the ventral surface, however, the lateral margins of the foot are commonly folded over to form temporary channels extending down the length of the foot. A movement of water in these folds can be demonstrated as the animal retracts. As the anterior part of the foot is retracted first it is conceivable that the folds might conduct water from any of the three sources mentioned above, or from all of them.

By introducing a soft piece of plastic catheter through the siphon, it is possible to draw off the water contained in the mantle cavity and to measure its volume, which is somewhat more than half the volume of fluid expelled when the snail retracts. However, when a snail is caused to retract after removal of the mantle water, the volume of the resulting jet is only approximately one-third less than in normal circumstances. We are thus of the opinion that water from the mantle cavity contributes to the jet but that some water remains in the cavity after retraction. The volume of the "free space" does not appear to be great and we have not been able to extract water from it. The proboscis sheath, however, contains a surprising amount of water, the exact volume of which has proved impossible to measure accurately. The introduction of coloured substances into these various spaces with subsequent attempts to recover them from the expelled fluid has proved fruitless as even the smallest particles (of carmine or indian ink) become entangled in copious mucous secretions; coloured fluids have led to equally negative results, for one reason or another.

The foot of *Bullia*, then, achieves expansion in the usual way—by the introduction of hæmolymph. Sea-water accounts for a small fraction of its total volume when expanded, but it is difficult to see what part this water can play in the mechanism of expansion; indeed it may well serve some other function altogether. The water which is expelled as a jet on contraction is probably a defence mechanism and is drawn from several parts of the animal, almost certainly including the foot's "aquiferous spaces" and the mantle cavity, and possibly including the proboscis sheath and the "free space". We are of the opinion that hæmolymph does not contribute to the volume of expelled fluid even during the most rapid contraction as hæmocytes have not been found in it and it reacts negatively to tests for protein.

We thank Dr. L. H. Hyman, of the New York Museum of Natural History, for her advice.

VETERINARY SCIENCE

Polysaccharide Haptens from Urine of Cattle infected with *Mycoplasma mycoides*

SERUM, plasma, lysed blood cells, urine and pleural fluid or 'lymph' (inflammatory exudate) were obtained from cattle naturally and experimentally infected with *Mycoplasma mycoides*. These materials were examined for antigens of *M. mycoides* by means of the agar-gel double diffusion precipitin test and the quantitative agar-gel precipitin test[1]. They were also examined for antibodies against *M. mycoides* by means of the complement fixation test[2] and the slide agglutination test[3], and for viable *M. mycoides* by growth in broth cultures.

Immune sera were prepared in sheep and cattle by intravenous injections of washed organisms grown in tryptose broth medium which contained no bovine antigens[4]. Sheep developed only a transient pyrexia during immunization. Cattle were initially inoculated with an avianized vaccine and reacted severely to subcutaneous challenge[5] prior to final intravenous immunization.

Urine samples from both naturally and experimentally infected cattle contained no antibodies and no viable organisms. Precipitating antigens, however, were consistently demonstrated and those in the urine of natural and experimental cases appeared to be identical. At least 2 precipitating antigens present in other body fluids were absent from the urine, but those in the urine were present in all the other body fluids.

Fractionation of pooled urine from experimentally infected cattle by precipitation with 3 and 6 volumes of cold isopropyl alcohol and deproteinization with a chloroform–butanol mixture[6] produced 4 precipitating antigens in the 2 fractions. Each fraction contained 3 antigens, 2 antigens being common to both fractions.

Both the fractions were Molisch-positive, biuret-negative, complement-fixing, relatively non-toxic in mice and rabbits, pyrogenic in rabbits and both were haptens as they failed to produce antibodies in rabbits and mice.

Work is in progress to try to elucidate the part, if any, that these haptens play in pathogenesis and immunity. It is also intended to investigate the remaining antigens in the other body fluids.

MICROBIOLOGY

A Calcium-sensitive Strain of *Rhizobium trifolii*

CONTRARY to the findings of Norris[1], it has been possible to show regularly, in detailed growth investigations, a favourable response to calcium by strains of *R. trifolii* and *R. meliloti*. This has expressed itself as faster and more sustained growth in the exponential phase and in a greater stationary population. Calcium is also needed for the normal rod-shaped cell, compared with the markedly swollen and vacuolated condition which is a characteristic result of calcium deficiency[2].

Recently, however, a variant form of *R. trifolii*, strain *SU* 298/531, has been encountered which is markedly sensitive to calcium when grown in the same defined medium as otherwise permits the favourable response to be demonstrated. The calcium-sensitive variant is recognizable as a different colony form but shows serological behaviour similar to the parent strain as well as retaining its ability to nodulate species of *Trifolium*. Typical growth data with single colony re-isolates of the parent and variant colony types are given in Fig. 1.

The parent type shows a normal sustained favourable response to calcium. The sensitive variant, on the other hand, though responding early to calcium, soon ceases growing in the presence of that ion and is surpassed by the culture growing in its absence.

R. trifolii, *SU* 298, and the sub-strains derived from it, are the lysogenic cultures described by Marshall[3]. The early cessation of growth seen here in the presence of calcium could well reflect a disturbance of the normal 'symbiosis' between prophage and

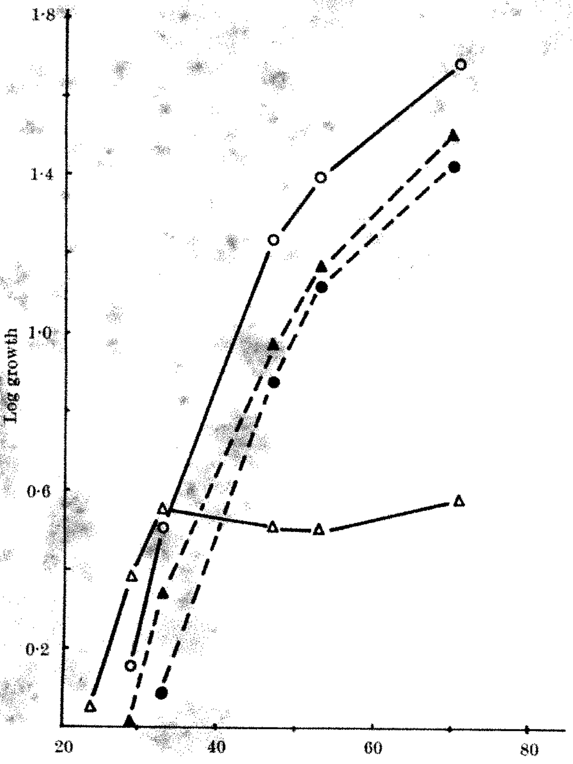

Fig. 1. Response of parent and sensitive strains to calcium. ○, Parent strain + calcium; ▲, sensitive strain − calcium; ●, parent strain − calcium; △, sensitive strain + calcium

bacterium, such that a considerable part of the population autolyses and keeps the turbidity low. The detailed nature of the phenomenon has by no means been defined. The occurrence of sporadic departures from the condition we have described indicates this, but results to date show that this calcium sensitivity is dependent on pH (pH 6 > pH 6·5 > pH 7·0), and is avoided by the addition of glutamate to the medium and by the associated growth of parent-type cells.

Calcium Requirement for Growth of *Staphylococcus pyogenes*

WHETHER calcium is an element essential for bacteria is uncertain. Gorini and Audrain[1] concluded that *Bacillus megatherium* needed calcium only when proteolytic enzymes were used to obtain amino-acids; the results of Shooter and Wyatt[2] with *Staphylococcus pyogenes* were explained similarly. *Diplococcus pneumoniae* also requires calcium[3]. There is no evidence that calcium is required intracellularly although Haines[4] showed that it was required for the formation but not for the activation of bacterial proteases. We have attempted to show the uptake of calcium by a *Staphylococcus* by use of the radioactive isotope calcium-47.

A 0·5 per cent glucose, 1·5 per cent tryptone broth was depleted of cations, except Na^+, by passing it through ion-exchange resins (in preparation). The Ca^{2+} remaining in the medium was not detectable by chemical methods or flame photometry; previous results[2] led us to conclude that the residual Ca^{2+} was about 1 μM. Additions of 'Specpure' salts (Johnson, Matthey, Ltd., London), including calcium chloride, were made; all tubes contained calcium-47 (Radiochemical Centre, Amersham) supplied as calcium chloride in isotonic saline. After dilution with distilled water, the total concentration of radioactive isotope and carrier was 0·25 μM Ca^{2+}. About 23,000 bacteria were added per 10-ml. medium (in preparation); the cultures were incubated at 37° C., 5-ml. samples were taken, centrifuged at 1,000g for 20 min. at 15° C.; 2 ml. of supernatant was withdrawn and diluted to 10 ml. These solutions were counted in a liquid Geiger–Müller counter, type M6, which gave about 600 counts/min. for a concentration of calcium-47 of 1 μc./l. Counting times were such as to give a statistical accuracy of 1·5 per cent or better.

In the first experiment, sixteen combinations of cations were tested and the growth with each combination is shown in Table 1. There was no significant difference between the activities of the supernatants after growth and those of the uninoculated controls (Table 2). In the experimental supernatants all except the two extreme counts/min. of 500 and 570 fell within the range of the controls. The range of activities showed no dependence on the combinations of cations added or on the total Ca^{2+} added.

Table 1. GROWTH OF *Staphylococcus pyogenes* WITH THE COMBINATION OF CATIONS USED FOR MEASURING CA^{2+} UPTAKE

No. of results	(16)	(9)
Range	500–570	519–547

Analysis of variance: standard error of the difference = 4·4.

The possibility that Ca^{2+} might be needed only at an early stage in growth and later released was also examined. In a subsequent experiment, tubes containing 0·1 mM K^+ and 1 mM Mg^{2+} were incubated for 10, 15, 18 and 24 hr.; Spekker readings of growth were 0·073, 0·198, 0·291 and 0·345 respectively. As before, there was no significant difference between the activities of the supernatants from these tubes and those of the controls.

These results suggest that although addition of Ca^{2+} can increase growth by more than 30 per cent, no accumulation of Ca^{2+} can be detected even in very small concentrations of Ca^{2+}. The following possibilities may be considered:

(1) That Ca^{2+} is required extracellularly.

(2) That Ca^{2+} is required intracellularly in trace quantities only. With the method used here, an

uptake greater than 4 per cent or 0·4 µmole Ca^{2+}/gm. dry wt. cells might have been detected. This would represent an accumulation greater than 125 times the supernatant concentration, with no extra added calcium and no accumulation with 100 μM Ca^{2+} added. This is based on a total cell volume of 2·67 ml./gm. dry wt. (the cell pad volume 3·61 ml./gm. (ref. 5) less 26 per cent interspace volume for close-packed spheres[6]). As the counts of supernatants and controls agree closely, it is probable that uptake was much less and the accumulation without added Ca^{2+} was as low as ten-fold.

(3) That calcium is not needed as such, but in media containing chelating agents, for example, amino-acids, displaces another cation that is required.

There is some support for the third possibility, for experiments with two different media and three strains of *Staphylococci* have shown that Fe^{2+} is as effective as Ca^{2+} in promoting growth. However, for equal effects on growth, equimolar concentrations of them are needed[7], and as the relative affinity of chelates for Fe^{2+} is very much greater than for Ca^{2+}, this makes displacement by Ca^{2+} doubtful. It is more probable that Fe^{2+} and Ca^{2+} are required for enzymes on alternative pathways.

Fixed Pathogenic *L* Forms of *Agrobacterium tumefaciens*

Unstable *L* forms of *Agrobacterium tumefaciens* (strain *B*.38) induced by glycine have been described by Rubio-Huertos and Desjardins[1]. In the present work two strains, *A.T.B.* and *A.T.* isolated from grapes, were grown in agar plates with 4 per cent glycine, where they readily formed typical *L* colonies. These were transferred simultaneously at intervals of 2–3 days to new plates of agar–glycine and glucose–agar without glycine. On the fiftieth transfer no reversion to the normal bacillary form was observed even after 32 further transfers in medium without glycine. The fixed colonies, formed by spherically dense elements, have the same macroscopical appearance as the normal colonies of *A. tumefaciens* grown in the same medium and have lost the typical features of the *L* colonies.

The fixed spherical forms were observed using both light- and electron-microscopes (Fig. 1); they appear to have a definite plastic membrane similar to the *L* forms, more dense cytoplasm and a slime layer; they are also of a more regular size, 0·5–0·8µ, unlike the unstable *L* colonies formed by elements of very different sizes.

Inoculations with the fixed forms of small plants of *Phaseolus vulgaris* gave a positive pathogenic response, and the same type of spherical forms were recovered from the tumours.

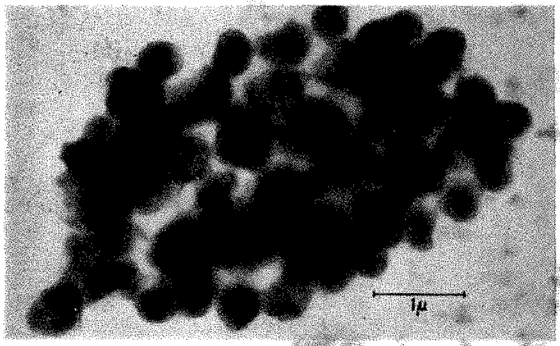

Fig. 1. Electron micrograph of fixed spherical elements of *A. tumefaciens*

The crown-gall tumours induced by spherical forms are of the same size and similar macroscopic appearance as those induced by the normal bacillary parental strains of *A. tumefaciens*.

The pathogeneity of unstable *L* forms could not be proved here because only normal bacillary forms were recovered from the tumours induced by inoculation with these unstable forms. The pathogeneity of *L* forms has been reported in animal pathogen bacteria (Lavillaureix[2], Rubio-Huertos and González[3]), but the pathogeneity of the fixed spherical forms of *A. tumefaciens* is the first case, so far as we know, for plant pathogens.

Comparative tests for sugar fermentation, and other physiological essays revealed that there is no difference between the fixed spherical forms and the normal parental strains.

The pathogenic spherical elements forming the fixed colonies fulfil all the requirements stated by Klieneberger-Nobel[4] for *L* forms except in the macroscopical morphology of their colonies. Thus it is difficult to say if they are real *L* forms or an induced spherical mutant of the normal parental strains.

PSYCHOLOGY

Auditory and Visual Interaction in Man

Some characteristics of auditory and visual interaction were studied in 36 normal young adult subjects, using a method based on recognition of repetitions. This method extends and complements procedures developed by Averback and Sperling[1], Broadbent[2], and Shepard and Teghtsoonian[3].

The stimuli used were supra-threshold ½ sec. auditory and visual presentations of randomly selected numbers from 1 to 7 and 10 to 17. The subjects were presented with 32 short groups of 9 sequential displays, one display every 2 sec. Each display consisted of the simultaneous auditory and visual presentation of two different numbers. Four of the last eight displays of each group contained either a visually or an aurally presented number which was a repetition of a previous presentation within the same group. Repetitions followed two displays after initial presentation, but the subjects were not aware of this. Half the repetitions were aural and half were visual presentations; half of both types of repetition were of numbers initially presented aurally and half visually. The subjects were instructed to press a micro-switch when they noted any repetition of any number already seen or heard.

The principal results were: (1) Auditory and visual probing repetitions were equally well recognized, each accounting for half the total information retrieved from immediate memory storage. (2) While recognition of repetitions of both auditory and visual input declines as more information is added to short-term storage, only 59·5 per cent of visual input was recognized when repeated in contrast to 76·2 per cent of aural input. This difference is significant by the *t*-test ($P < 0{\cdot}01$). (3) Auditory information was retrieved equally well by both auditory and visual probe repetition ($P > 0{\cdot}05$ by the *t*-test). Visual repetition retrieved a significant 4 per cent more of the total visual information retrieved than did auditory repetition ($P < 0{\cdot}01$ by the *t*-test).

The considerable degree of auditory-visual interaction revealed by these results may be due in part to the particular procedure of this experiment which reflects interaction only in immediate memory. It may also be due to the use of numbers as stimuli; these factors might account for results differing from those of Cole, Chorover and Ettlinger[4]. Furthermore, these stimuli were supra-threshold, as demonstrated by 98·6 per cent correct responses by these subjects in a control test in which they had to indicate only if any two numbers simultaneously seen and heard were identical.

I thank Dr. Murray Jarvick (U.S. Public Health Service grant *M*-1225) and Dr. Josiah Macy, jun. (who with Miss Maria Ungson provided the statistical analysis under National Institutes of Health grant *B*-3491).

Short-term Retention of more than one Aspect of a Series of Stimuli

IT has been found that subjects recalling sequences of digits presented in pairs simultaneously to two sense organs (the two ears, or eye and ear)[1,2] show preferences between strategies of recall which have been attributed by Broadbent[3] to the existence of at least two selectively acting storage systems.

A model for this process envisages the organism as selecting between 'channels' of input. It is not clear whether such 'channelling' of stimuli entails identifications more complex than grouping by source, or to what extent the model may be extended to other processes of selective attention. A situation where subjects are required to recall more than one aspect of a series of stimuli is therefore a test case.

Fifty-two cards measuring 3½ in. × 2¾ in. were each stencilled with a single letter of the alphabet in 72-point Bodoni bold capitals. The letters made up two alphabets, one stencilled in red and the other in black. By shuffling the cards, and dealing them face upwards in time to a metronome at intervals of 0·75 sec., so that each card covered its predecessor, subjects were presented with sequences of 5 letters in random order, each letter being randomly either red or black.

Subjects were required to recall two stimulus aspects independently, reporting the colours in the order of presentation (for example, 'red–black–red–red–black'), and the letters also in the order in which they were presented (for example, '*A–B–C–D–E*'). Instructions were varied so that subjects either reported the letters first and the colours second, or vice versa. Two conditions of instructions were compared: in Condition 1 subjects were told the required order of recall before the items were presented. In Condition 2 subjects were told the required order of recall after the items were presented.

Here Broadbent's model for selection between sources predicts that where the order of recall is known in advance, recall of the first group of items reported (letters or colours in this case) will be better, and recall of the second group of items will be worse than for their equivalents in a condition in which order of recall is not known until after presentation.

Eighteen postmen aged 17–29 years were given 100 trials on each of these conditions. The two orders of recall ('colours first' or 'letters first') occurred equally often in series randomized by transposition from tables of random numbers. Nine subjects started with Condition 1 and nine with Condition 2. All departures from presented sequences were classed as errors.

Results are presented in Table 1.

Table 1. COMPARISON OF KNOWN AND UNKNOWN ORDER OF RECALL FOR GROUPED STIMULUS ASPECTS—MEAN CORRECT RECALL

	Condition 1. Order of recall known in advance (per cent)	Condition 2. Order of recall not known in advance (per cent)
Colours first	87	79
Colours second	72	76
Letters first	83	70
Letters second	49	62

A Wilcoxon test[4] confirms that both colours and letters, when reported first, are significantly better recalled in the known than in the unknown order of recall condition ($P < 0{\cdot}01$ two-tailed). Conversely, both aspects, when reported second, are significantly better recalled in the unknown order of recall condition ($P < 0{\cdot}01$ two-tailed).

These results show an effect similar to that demonstrated by Broadbent[2] for selection between two stimulus sources. They may only be accounted for by a theory of independent storage systems if the definition of what constitutes a 'channel'[1-3] for selection and identification of stimuli is extended to cover a considerably wider field of behaviour than that to which it was first applied.

FORTHCOMING EVENTS

Monday, July 9—Thursday, July 12

British Institution of Radio Engineers, Institute of Physics and the Physical Society, and the University of Birmingham (in the Electrical Engineering Department, The University, Birmingham)—Symposium on "Sonar Systems"

Thursday, July 12—Friday, July 13

Biochemical Society (at the Department of Biochemistry, University of Cambridge) at 9 30 a m daily—International Meeting

Thursday, July 12 at 2 15 p m —Colloquium on "Control of Protein Biosynthesis—the Role of Nucleic Acid"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Tutorial Research Fellow or Student in Chemistry—The Secretary, Bedford College (University of London), Regent's Park, London, N W 1 (July 12)

Staff Tutor in Physics in the Department of Extra-Mural Studies—The Registrar and Secretary, The University, Bristol (July 14)

Assistant Lecturer in Physiology—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W 8 (July 16).

Assistant Lecturer (with interests in ecology, cytology or virology) in Botany—The Registrar, The University, Hull (July 16)

Research Assistant (with a special interest in geomorphology or historical geography) in the Department of Geography—The Secretary, University College, Gower Street, London, W C 1 (July 16)

Sub-Librarian (with a good honours degree, and preferably relevant experience and professional qualifications) in the Faculty of Engineering—The Registrar, The University, Liverpool, quoting Ref CV/122 (July 16)

Lecturer (with a good honours degree in physics or mathematics and some experience in research) in Astronomy—The Secretary, The University, Edinburgh (July 18)

Assistant Lecturers in Philosophy and Chemistry—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (July 20)

Research Demonstrator in the Department of Physics to undertake teaching duties under supervision (mainly in practical classes), participate in the research of the department, and to study for a higher degree—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (July 20)

Assistant in the Department of Zoology and the Gatty Marine Laboratory, St Salvator's College (candidates with specialist interest in entomology should *not* apply)—The Secretary, The University, College Gate, St Andrews (July 21)

Lecturer or Assistant Lecturer in Bacteriology—The Registrar, The University, Manchester, 13 (July 21)

Research Assistant in Veterinary Preventive Medicine to work at the Veterinary Field Station on a programme of research dealing with respiratory diseases in poultry—The Registrar, The University, Liverpool, quoting Ref CV/118 (July 21)

Assistant Experimental Officers (with a degree in chemistry and/or botany, A R I C , or H N C.) for analytical work with crops, soils and fertilizers and for work on crops grown in glasshouse experiments—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (July 23)

Assistant Lecturer in Applied Mathematics—The Secretary, Birkbeck College (University of London), Malet Street, London, W C 1 (July 23)

Lecturer in the Department of Zoology—The Registrar, University College of Wales, Aberystwyth (July 23)

Lecturer or Assistant Lecturer (preferably with experience in the field of nuclear magnetic resonance) in Inorganic Chemistry—The Registrar, The University, Leicester (July 24)

Physical Chemist (with a first- or second-class honours degree in physical chemistry or general chemistry with the emphasis on the physical side) to work on physico-chemical aspects of soil-plant-nutrient relationships—The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (July 25)

Lecturer or Assistant Lecturer in Mathematics at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (July 31)

Senior Lecturer or Lecturer in Mathematics in the School of General Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, July 31)

University Lecturer (with qualifications in numerical analysis or computer programming) in the Mathematical Laboratory—The Director, Mathematical Laboratory, The University, Cambridge (July 31)

Fellow/Lecturer in Anthropology—The Registrar and Secretary, The University, 38 North Bailey, Durham (August 1)

Senior Lecturer or Lecturer in Psychology at the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1, and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town (August 10)

Assistant Lecturer (with an honours degree in archæology or equivalent, and a good general knowledge of European and British prehistory with emphasis on the periods before the Neolithic) in the Department of Archæology—The Secretary, The University, Edinburgh (August 11)

Chair of Eye Health in the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, August 31)

Lecturer in Veterinary Preventive Medicine—The Registrar, The University, Liverpool, quoting Ref CV/117 (August 31)

Senior Lecturer in Zoology at the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1, and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town (August 31)

University Assistant Lecturer (with a degree in psychology, some post-graduate experience, and some knowledge of statistical methods) in the Department of Education—The Secretary, Cambridge University Department of Education, 17 Brookside, Cambridge (September 1)

Head (with appropriate academic qualifications and experience) of the Department of Science and Food Technology—The Principal, Salford Technical College, Peel Park, Salford, 5

Lecturer (with a university degree or equivalent qualifications) in Metallurgy, to teach foundry technology and refractory materials to final year degree and diploma in technology students—The Clerk to the Governing Body, Battersea College of Technology, London, S W 11

Reader in Medical Parasitology at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, W C 1 (September 18)

Senior Lecturer (well qualified academically with adequate industrial and/or research experience) in Aerodynamics—Head of the Department of Aeronautics and Space Technology, Northampton College of Advanced Technology, St John Street, London, E C 1

BRITISH TECHNICAL CO-OPERATION OVERSEAS

THE White Paper on future policy in recruitment for service overseas which the Department of Technical Co-operation has recently issued is of interest for two main reasons First, for its exposition of the principles which the Department is using and proposes to use in future for the recruitment of staff for scientific research and other professional service overseas Secondly, for its indication of the scale of such recruitment, of which the surveys of scientific and technical manpower have hitherto given no indication In 1961 some 581 appointments to the British Overseas Dependent Territories were made through the Department compared with 816 made in 1960 through the Colonial Office, 1,083 in 1959, 1,335 in 1958, and 1,367 in 1957 During the same period, 188 appointments were made under the Colombo Plan to India, Pakistan, Ceylon and Malaya, the annual total varying from 28 in 1959 to 49 in 1957, appointments made from Britain under the Plan to Burma, Laos, Indonesia, Cambodia, Vietnam, Nepal and Thailand totalled 69 Under the Special Commonwealth Africa Assistance Plan coming into operation in 1960 and earlier bilateral arrangements, 107 appointments have been made to Ghana, Nigeria and Sierra Leone Some 7 appointments have been made to Liberia, Guinea, Ivory Coast and Togoland under the Foundation for Mutual Assistance in Africa South of the Sahara, while not counting re-appointments, 57 long-term and 56 short-term appointments have been made to Turkey, Iran and Pakistan under the Central Treaty Organization (Cento)

In addition to this total of 5,659 appointments since 1957, Britain has supplied a further 14 short-term (non-Cento) appointments to Middle Eastern countries and 132 appointments to the Middle East and North Africa as well as 97 to United Nations and other international technical assistance assignments These figures show that the British contribution is not negligible either in relation to technical assistance as such or in relation to Britain's resources of scientific and technical manpower, if in scientific research, in particular, the total is unlikely ever to be large, it is important that conditions should be such as to ensure a flow of candidates of appropriate qualifications The White Paper rightly examines these conditions and the action being taken in respect of particular categories of recruitment, and the information it collects should be widely circulated and noted by the professional organizations concerned

It is recognized, for example, that if the needs of existing and projected universities in Africa and elsewhere are to be met, arrangements for the supply of staff for comparatively short periods will be important, and in co-operation with the British Council, the Department has set up a new body, under the chairmanship of Sir Charles Morris, to encourage and facilitate the supply of staff on a short-term basis through home universities Funds provided under the Commonwealth Teachers Act will be available, where necessary, to initiate projected schemes Again, in April last the Council for Technical Education and Training for Courses was established, with Mr F J Pedler as chairman, to give advice and expert assistance to the Government with the view of promoting technical and commercial education and training for developing countries This would include the provision of advice and information and promotion of contacts between those concerned with such education and training, the promotion and, where appropriate, undertaking of recruitment of staff for service overseas in this field and facilitating the training and education in the United Kingdom of trainees, teachers and others from developing countries The Department of Technical Co-operation will look to this new Council as its main channel of recruiting technical education staff from Britain for Government and other institutions overseas at technical institute level and above

The importance of the work of both these two new bodies is well brought out in the admirable article on the university and technical assistance which Dr R S Morison contributed to the spring issue of *Daedalus* Although he addressed his appeal in the first instance to the Massachusetts Institute of Technology, he made it clear that the part a great university can play in this field goes far beyond co-operating in the secondment of staff, and includes a fresh look at the organization of research itself and the functions and location of the research institute The Department of Technical Co-operation appears to be well aware of the problems that arise here, and in an important passage it examines some of those that are involved in the secondment overseas of staff from home-based establishments for scientific research in tropical countries, either for cadre posts on the establishment of an overseas Government or research organization, or for limited periods to investigate a particular problem

On a small but effective scale, the White Paper points out, pools of research workers have been established for some years in Britain from which experts can be drawn to tackle problems which arise in the dependent territories in certain specialized fields These pools are based on institutions in Britain, and during the periods spent in such institutions members of the pools are under the direction of the director of the institute concerned While financial provision for staffing and operating the pools has been made from Colonial Development and Welfare Funds, the financial responsibility on assignment to a dependent territory normally rests with the employing Government There are five such pools—entomologists, plant pathologists, soil scientists, stored products research workers and pesticides chemists—and they are based respectively on the Commonwealth Institute of Entomology, the

Commonwealth Mycological Institute, Rothamsted Experimental Station, the Pest Infestation Laboratory and the Tropical Products Institute, and there is also an additional post at the Fisheries Laboratory, Lowestoft, to permit the acceptance and study at the Laboratory of overseas problems.

Over a broader field, the Overseas Research Council has examined the problem of the recruitment and retention of expatriate research workers overseas and has concurred in a scheme, now officially accepted, advanced by the Medical Research Council. In this, provision will be made first to encourage a number of senior men overseas to continue in their work by providing them with a home base when their posting overseas would normally expire, secondly, to encourage senior specialized staff recruited to a home base cadre to work abroad, and thirdly, to encourage young research workers to take posts overseas while holding an appointment with the Council. At the instance of the Overseas Research Council, the Agricultural Research Council, too, has examined the possibility of tackling similar problems in agricultural research in the emerging countries of the Commonwealth and it has been agreed that the Agricultural Research Council may make conditional offers of future employment to selected scientists who would, if their overseas service terminated, be particularly suitable to fill vacancies under the Council.

The recent Commission on the Most Suitable Structure for the Management, Direction and Financing of Research on an East African Basis, over which Prof. A. C. Frazer presided, recognized that it would be necessary to recruit expatriate staff of high quality to maintain the interterritorial research services in East Africa for the next fifteen years*. Furthermore, for much longer it might be necessary to recruit a proportion of staff from outside East Africa to provide the wide range of specialized knowledge and experience needed. The Commission suggested that the United Kingdom Research Councils could encourage recruitment by offering a form of dormant contract which would assure, for example, two years employment in the United Kingdom at the end of the East African contract if the recruit did not wish to continue in overseas services. A system of dormant contracts is also suggested to ensure the retention of the services of experienced expatriate research workers in the East African Interterritorial Research Organizations, and also to assist the recruitment and retention of sufficient expatriate technicians to meet the needs of research and to expedite an East African technical training scheme.

These and other recommendations of the Frazer Report are still under consideration by the Governments of Kenya, Tanganyika, Uganda and Britain, and each of these Governments hopes to deal with the recommendations at an early date. Besides dealing with this question of staff they cover the organization of research and the maintenance of the interterritorial research organizations which are considered in a world as well as a territorial context. Some simplification in structure is suggested through the replacement of the existing interterritorial research councils by two new ones, the East African Medical Research Council and the East African Natural Resources Research Council, while formation of an East African Industrial Research Council should be considered. The crucial difficulty is finance. While the value of the Tropical Pesticides Research Institute at Arusha is fully recognized and its continuation recommended, the territories have stated that they cannot afford to provide support for this institute.

Even more serious is the position of fisheries research. Since the Frazer Report was issued the decision was taken last March to close the East African Marine Fisheries Research Organization at Zanzibar in face of the Commission's recommendation that the work should be continued for at least another three years and only a month before the station was to play a major part in the international expedition in the Indian Ocean. Fishery research stations at Freetown and Singapore were also closed when the territories concerned became responsible for their own affairs, although capital costs of laboratories and boats at all three stations have been met entirely by Britain out of Colonial Development and Welfare Funds. At Zanzibar ten years of valuable work had been completed, and it is clear that where the objectives are long-range—even when the results have had invaluable bearing on nutrition and the raising of standards of living—scientific and technical considerations alone are insufficient to ensure the maintenance of the work. Financial stringency is only too likely to lead to political considerations and the desire for rapid results to cause action detrimental to the long-term interests of the community.

Consideration of the position of fisheries research alone fully endorses much that Dr. Morison has argued as to the importance of the university in technical assistance, and it also demonstrates the vital importance of the work which is being undertaken by the Department of Technical Co-operation. That has recently been described in a progress report issued by the new Department*, but at the same time the experience suggests that it is not altogether sound policy to give aid only at the request of the country concerned. Fisheries research, if not also pesticides research, suggests that the emergent territories are not invariably aware of their needs, and that there are problems in which it should be possible to offer aid tactfully without being either arbitrary or dictatorial. In these problems, too, the organization of support on an international basis is not always simple or effective.

This is not to deny that the overseas countries themselves should say what help they most need, and it applies essentially to one only of the twelve main heads of technical assistance set out in the White Paper as showing broadly what the nation's efforts should be most closely geared to supply—the development of scientific research. It is worth noting that in this White Paper reference is again made to the contribution of the Overseas Research Council in matters of general policy, and it would seem that the Department of Technical Co-operation will not neglect that Council, which, from the White Paper, is fully alive to the importance of scientific research in overseas countries and is ready to assist with specialist advice, advisory visits, conferences to exchange information, training scientists from overseas in universities and research institutions in Britain, recruiting scientific staff from Britain, and support for existing research services overseas. The other main heads listed are: training of public servants, supply of university and secondary school teachers and staff for teacher training colleges, technical education and training, staff and training for economic and financial planning, geodetic and topographical surveys, geological surveys, and help in developing mineral resources, supply of staff, advice and training to develop agricultural and other resources, advice, staff and training for industrial development, engineering surveys and assistance in telecommunications, supply of qualified medical and nursing staff, and medical and nursing training, management training, and individual service overseas through voluntary societies.

---

* East Africa High Commission. Report of the Commission on the Most Suitable Structure for the Management, Direction and Financing of Research on an East African Basis. Under the chairmanship of Prof. A. C. Frazer. Pp. xii+76. (Nairobi: Government Printer, 1961.) 5s.

* Department of Technical Co-operation. *Technical Co-operation: a Progress Report by the New Department.* Pp. 18. (Cmnd. 1698.) (London: H.M.S.O., 1962.) 1s. 3d. net.

The Department is seeking to secure that the technical assistance provided by Britain as a whole is properly focused on the needs of those it is seeking to help, and to remove some of the obstacles which hinder the free flow of such assistance. It cannot, however, hope to succeed in its task without the understanding and continued support and enthusiasm of many men and women in Britain, and of firms, voluntary societies, local authorities, professional, scientific and educational institutions and a wide range of organizations. These two White Papers provide an instalment of the publicity on which informed criticism and public support must be based. They deserve the attention of scientists and technologists and their professional institutions generally as well as of the universities, technical colleges and other research centres.

SCIENTISTS IN AMERICA

American Men of Science

A Biographical Directory. Edited by Jaques Cattell. The Physical and Biological Sciences. Tenth edition. A–E. Pp. ix+1–1126. F–K. Pp. 1127–2284. L–R. Pp. 2285–3510. S–Z. Pp. 3511–4586. (Temple, Arizona: The Jaques Cattell Press, Inc., Annex 15, Arizona State University, 1960 and 1961.)

THE tenth edition of this monumental work is now well on its way as a published reference book of prime importance.

But its title is a misnomer, yet, *American Men of Science: a Biographical Directory* is now so thoroughly entrenched among to-day's scientific literature, both because of the esteem in which it is held and owing to its traditional background (it was first published in 1906), that one cannot expect, nor would one wish to see, any basic change in the title-page. Nevertheless, it is not mere querulous criticism to direct attention to the misleading title because for the benefit of the most recent, and future recruits to the scientific fold, it should be emphasized that quite a distinct percentage of entries in this great 'Who's Who of Science' refers to people who are not Americans. There are, for example, biographies of men of science from other countries who, though now working and perhaps permanently settled in what was once known as 'The New World', still and perhaps always will for various reasons, prefer to retain their original nationality. Scientists in Canada are also included. Moreover, the editors have, quite wisely, not confined themselves to the continent of America so it is as well that the user should be up to date with his political geography, for here the fiftieth State is included—and some elegant scientific work is now being promoted in the University and various industrial (mainly agricultural) laboratories and fields in Hawaii.

Moreover, there are some distinguished American women of science, they also are included.

We consider it desirable to point out these features in order to emphasize the comprehensive nature of this great publication. The editors have clearly ignored the mischievous editorial adage 'When in doubt, leave out', and have spread their net very widely indeed, not restricting themselves as some new inquirer might naturally assume, to the United States of America. The area thus covered is wide indeed, but the editors have also delved deeply, for entries are devoted not solely to practical scientific workers in field and laboratory. Naturally, all the universities and more important colleges are covered and so also are Federal and State institutions (such as the renowned National Institutes of Health at Bethesda), the Armed Forces, museums and industry. Most of the personnel included in such organizations are an obvious choice for inclusion, but *American Men of Science* goes even deeper and includes others who are working for the advancement of science (most probably not at the laboratory bench) such as the various Foundations (for example, the Rockefeller and National Science Foundations). So also are people concerned with scientific publications. There are even some entries from high schools.

In the first edition of this valuable work of reference there were 4,000 biographies, the tenth edition, when completed, will contain 120,000.

The ninth edition was divided into three volumes: (1) Physical Sciences, (2) Biological Sciences, (3) Social and Behavioral Sciences. It was a wise decision partially to modify this classification in the new edition, for so much has science advanced, and so much do the multitude of scientific disciplines now overlap, that to-day there are many distinguished scientists who, quite justifiably, could be placed in two, perhaps even all three, of the former, ninth-edition volumes.

The tenth edition is to be divided into five volumes. The first four now published, cover the physical and biological sciences—such terms being very widely interpreted. It is hoped to publish the fifth and final volume later this year; this will comprise the social and behavioural sciences. It is conceivable that in due course the editors will decide to jettison even these two categories (social and behavioural). We note, for example in the present physical and biological sciences volume, A–E, the name of a psychiatrist whose main field of interest is stated to be psychiatry and religion. When this book is completed and the fifth volume appears, we can well imagine an inquirer referring to the fifth volume for this entry So perhaps the editors, when preparing the eleventh edition of *American Men of Science,* will seriously consider no divisions at all, but to produce the work in a convenient number of volumes with all entries going straight from A to Z In this case, once the scientist's name is known, the inquirer can immediately select the right volume before he opens its pages

Each entry gives in capital type the name, present professional position and special field of scientific interest or activity Professional (and in many cases private) addresses are presented in smaller type so is the rest of the biography—place and date of birth, whether married, number of children (if any), membership of relevant committees, societies and academies (both at home and abroad), university degrees and any other distinctions, and finally the special scientific interests of the person being noted

American Men of Science is now well past its half-century of publication It was initiated by James McKeen Cattell, and first published as a manuscript reference list for the Carnegie Institution of Washington The founder of this great work was also at one time publisher and editor of the world-renowned American weekly journal, *Science* Eventually, *Science* was handed over to the American Association for the Advancement of Science, and is at present the responsibility of our friends, the secretary of the Association, Dael Wolfle (as publisher), and Dr Graham DuShane (as editor) We are sorry to learn that Graham DuShane is about to resign, but wish him well in the distinguished position he is about to occupy We would also like to take this opportunity of extending a welcoming hand to an equally distinguished scientist, Dr Philip Abelson, who is soon to succeed Graham DuShane in the editorial chair of *Science* (see also p 122 of this issue)

The founder of *American Men of Science,* Dr James McKeen Cattell, devoted more than thirty-five years to it, after which he was succeeded by his son, Jaques Cattell In 1958, Jaques transferred the publication of this work to the campus of Arizona State University at Tempe There, with the assistance of a great and expanding University, he began the production of this tenth edition It must have been a grievous loss to all concerned with this project when, in 1960, Jaques Cattell died However, his nephew, Garrison Cattell, continued the work as vice-president of the Jaques Cattell Press and with Mrs Dorothy Hancock as editor Then, last year, the Bowker Co of New York took over the Jaques Cattell Press This Company had already been publishing the ninth edition under Jaques's editorship, and now promises that it intends "to maintain and continue the work in Tempe and proceed with the plans made by Mr Cattell, maintaining the same close liaison with professional associations and holding the same high standards which have characterized this 'saga of American science' for more than half a century" This makes good reading, for though the "professional associations" concerned are senior in character, and, in this project, come under the auspices of the U S National Academy of Sciences—National Research Council and the American Association for the Advancement of Science, *American Men of Science* was conceived and reared, and has obviously ever since been cherished, by the family Cattell, to whom the entire world of science will always be indebted

BACTERIAL ENERGETICS

The Bacteria

A Treatise on Structure and Function Edited by I C Gunsalus and Roger Y Stanier Vol .2 Metabolism Pp xv + 572 (New York Academic Press Inc , London Academic Press, Inc (London) Ltd , 1961) 15 dollars

UNLIKE the first volume this one includes only one contribution from laboratories outside the United States But surely this sentence from the preface is not even American "Thus with the main emphasis shifted to other aspects of cellular behaviour, one may expect for energy metabolism that gaps in knowledge will eliminate gradually, and some hypotheses altered, but the bases for reasoning will, in the main, be sustained" One may wonder if by titling Volume 2 *Metabolism* and Volume 3 *Biosynthesis* we are to suppose that biosynthetic processes are non-metabolic, and if so, why do both volumes contain a chapter on photosynthesis In fact it is early pointed out that the aim of the volume is to provide an informed concept of the energy-liberating systems encountered in bacteria The large number of references to metabolic processes in yeasts is easily excused in view of the great volume of related and readily applicable information which has been obtained from the study of yeast systems

The book is divided overall into chapters dealing with fermentations, oxidations and 'light-involving' systems The first chapter is a very good general survey of "energy-yielding metabolism in bacteria", while those that follow deal in some detail with the fermentation of carbohydrates and nitrogenous compounds, cyclic mechanisms, dissimilation of high-molecular-weight compounds, microbial electron transport systems, aerobic and anaerobic cytochrome systems, cytochrome-independent systems, bacterial photosynthesis and luminescence The chapter on photosynthesis surveys the evidence obtained from experiments with chromatophore extracts, on this a general formulation of bacterial photosynthesis has been based and a comparison with plant photosynthesis made The discussion of carbon dioxide fixation has been left to Volume 3 The chapter on bacterial luminescence is of special interest for a number of reasons Comparatively little is heard about this fascinating property, and this chapter is engagingly and well written (except for "Pfluger demonstrated that the bacteria from fish was filterable") Bioluminescence is in many ways the reverse of photosynthesis and the light-energy emitted provides a visible indication of the metabolic activity of the cells which enables the effects of added metabolites, narcotics, etc , to be measured

The wealth of well-documented information in this volume illustrates once more the great utility o micro-organisms as objects of biological investigation Their very high metabolic rate coupled wit the advances made in radioisotopic methods hav enabled the whole tempo of biochemical discover to be increased and this volume is an excellent surve of the present state of these discoveries in regar to the energy supply of bacteria Unfortunately, th type of logic used in making conclusions about bio chemical activity in complex living systems does no permit one to state that the entire contents ar immutably true Some of the ideas expressed wi no doubt be modified, but it is because of publication of this kind that a realization of the whole truth wi be more speedily obtained.

A useful addition would have been a separate glossary for the numerous abbreviations used in the text. Policy on how they were to be introduced was undecided; in two chapters they are collected in a footnote on the first page, while in the rest they pop in and out of brackets. There are more than 1,700 references, and excellent author- and subject-indexes enhance its value to the practising biochemist while for the serious microbiologist in any field it provides the perfect reference book into which he will find himself continually delving in search of the fundamental explanation of his observations.

L. B. QUESNEL

NON-LINEAR CONTROL SYSTEMS

Stability in Nonlinear Control Systems

By Alexander M. Letov. Translated from the Russian by J. George Adashko. Pp. 316. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1961.) 68*s*. net.

THE Russian school of mathematical engineers is noted for the detailed and painstaking approach which it has made to many of the problems of control theory. This approach, and the use made of it in the U.S.S.R., differs markedly from the semi-empirical method which is customary in Britain and was, until quite recently, superior even to the American attitude to design.

In recent years translation of Russian papers and books have acted as a spur to Western engineering education and each new one is anxiously scanned to see if, to put it crudely, we have missed something!

One of the more significant of the recent translations for engineers is Popov's monumental *Dynamics of Automatic Control Systems*. This starts with the most elementary assumptions, both of previous knowledge of control systems and of the mathematical methods needed to discuss them, and is well suited to the needs of engineers trained in the British tradition.

Letov's book, dealing as it does with non-linear problems, is of a quite different kind. Naturally, a discussion of such material could scarcely be elementary, although some of the presentations given by Lefschetz and particularly by Cartwright, have at least the merit of being 'interesting enough' to encourage the reader to make the necessary effort. But the austere axiomatic and analytical approach of Letov makes the text one of the most difficult that I have encountered. To be fair it must be said that the formal mathematics needed to understand the book is quite limited; the difficulty lies, however, in the author's failure to relate his equations to the physical realities beloved of the engineer. There is scarcely a single 'number' in the book and no graph or diagram which is thought worthy of a scale or even a caption, a state of affairs which makes puzzling the remark, on the dust-jacket, that "—it does not hesitate to go into abundant details of computation . . ."

These criticisms should make it clear to readers of this review that the book is of far more use to mathematicians than to engineers. There are comprehensive discussions of Lyapunov's direct method for investigating stability, Hurwitz's theorem and Lure's transformations. The reduction of the equations of control systems to various Canonical forms is illustrated by reference to the problem of the 'Isodrome' regulator and, after discussing the stability of unsteady motion, the author examines the effects of velocity feedback and thus leads finally to an examination of the theory of the stability of the bicycle. Lest this everyday conclusion should raise hope of practical results it should be mentioned that the book ends with an analytical expression from which the reader is invited to decide the point for himself!

A. D. BOOTH

ANIMALS OF BRITAIN

Animals of Britain

No. 1: Badgers. By Dr. Ernest G. Neal. No. 2: Horseshoe Bats. By John Hooper. No. 3: Hedgehogs. By Maxwell Knight. No. 4: Water Voles. By Stéphanie Roden Ryder. No. 5: Grey Squirrels. By Monica Shorten. No. 6: Red Squirrels. By Monica Shorten. No. 7: Grey Seals. By H. R. Hewer. No. 8: Otters. By E. G. Neal.

Each number Pp. 24. (London: Sunday Times Publications, Ltd., 1962.) 3*s*. 6*d*.

THE Sunday Times Publications, Ltd., is producing a series of booklets called *Animals of Britain*. Altogether there will be about twenty-six booklets, each dealing with one animal (with the exception of bats, when eleven different species will be divided between four booklets). So far, eight booklets have been published; another eight will appear in the autumn, and the remainder at intervals thereafter. The series is edited by Dr. L. Harrison Matthews.

Those already available are *Badgers*, by E. G. Neal; *Horseshoe Bats*, by John Hooper; *Hedgehogs*, by Maxwell Knight; *Water Voles*, by S. R. Ryder; *Grey Squirrels*, by Monica Shorten; *Red Squirrels*, also by Monica Shorten; *Grey Seals*, by H. R. Hewer; and *Otters*, by E. G. Neal. It can be seen that many well-known naturalists appear among the authors.

Each booklet contains twenty-four pages. These are filled with a large number of black-and-white photographs, some informative diagrams and a detailed, though uncomplicated, text. Many of the photographs are unusual shots, including those of very young creatures and some, as yet, unborn. The diagrams are of such things as the layout of a badger's sett, the distribution of an animal, or comparisons. Except in Booklet No. 2, *Horseshoe Bats*, the text is subdivided under such headings as general appearance, distribution, habitat, food and feeding habits, the senses, breeding cycle, enemies, peculiarities, and general habits. This makes the text very easy to follow. In both *Hedgehogs* and *Red Squirrels* there is a section on legends. *Badgers*, *Grey Squirrels* and *Water Voles* contain sections suggesting how best to watch these animals. Hedgehogs as pets is another short section. Each booklet is concluded with a short list of books for further reading, and a full-page diagram of the skeleton of the animal.

The front cover of each booklet is attractive, with a colour photograph. The price is very reasonable, considering the information contained and the good presentation. Many adults will be interested to have all the details put before them in such a straightforward manner, and it will be an excellent and reliable series for schools to have in their libraries. Young naturalists are sure to be waiting in eager anticipation for the rest of the series to be published.

B. J. G. MAITLAND

Diagnostic Microbiology

A Textbook for the Isolation and Identification of Pathogenic Microorganisms By Prof W Robert Bailey and Elvyn G Scott Pp 327 (Saint Louis The C V Mosby Company, London Henry Kimpton, 1962) 48*s* 6*d*

THIS work is presented in ten parts, the first of which, a classification of the plant kingdom, is irrelevant and should be relegated to a work on taxonomy The second part, entitled "Laboratory Methods", consists of four chapters dealing superficially with the cultivation, microscopical study, staining and isolation of micro-organisms Three short chapters on the collection of specimens, their transport to the laboratory, and their handling there, comprise part three The fourth part, containing ten chapters, is concerned with the cultural isolation of pathogenic bacteria and *Candida albicans* from the natural cavities and ducts of the human body, from the blood and contaminated blood bank specimens, and from cerebrospinal fluid, wounds, morbid exudates, and autopsy material

Methods for the identification of these pathogens are discussed in the fourteen chapters embodied in the fifth part, which is succeeded by a brief sketch of laboratory procedures for the diagnosis of viral and rickettsial diseases There follows a somewhat more informative sketch of methods for the laboratory diagnosis of the systemic mycoses Part eight deals with antibiotic sensitivity tests and its successor with miscellaneous serological procedures The final part is divided into three chapters which deal with the composition and preparation of sixty-eight media, the formulæ and use of ten stains and two mounting fluids, and the composition and use of ten reagents respectively

Apart from a number of line drawings—of which the one depicting *Candida albicans* could be redrawn with advantage—in the mycoses section, the work is not illustrated The text is explicitly written and presented in clear type, but the work in general suffers from the attempt to cover too wide and varied a field in too small a compass, with the inevitable result that too little information is provided for graduate bacteriologists and it is too diffuse for students reading for degrees in medicine and dentistry As an introductory work it is useful for students taking a course in biology

J F D SHREWSBURY

Annual Review of Physical Chemistry

Vol 12 Edited by H Eyring in association with C J Christensen and H S Johnston Pp vii + 514 (Palo Alto, Calif Annual Reviews, Inc , 1961) 7 dollars

THIS volume give a brief summary of papers published in 1960 in many branches of physical chemistry Like the previous volumes in this series, it is valuable to research workers since it provides a concise and yet almost complete review of work done in a particular field All the volumes in the series also provide a useful starting point from which to review special topics The author-index and extensive subject-index are particularly useful in this respect

The editors have again selected a competent group of contributors who are largely from the United States The articles are essentially reviews rather than critical accounts of the subject, since the latter would require a book of considerably larger scope and size In keeping with the policy outlined in the preface of Volume 1 of the series, a new set of authors is selected again to obtain somewhat different points of view on subjects bordering on physical chemistry and to change the emphasis of the importance of any aspects of the subject according to the writer's point of view

The subjects selected for review vary from year to year according to current interest In comparing this with the 1960 volume, a new section on marine geochemistry by E D Goldberg is included The large aqueous chemical system comprising the world's oceans seems to be attracting the interest of many physical chemists at the present time A clear account is given of some of the chemical reactions which occur and the parameters which influence the course of such reactions Elemental and isotopic abundances are discussed, and in certain cases they appear to have remained constant for 2 5 × 10^8 years The change in present-day interests is also demonstrated by the omission of sections on chromatography and photosynthesis

The material of Volume 12 is well presented in clear print, as in previous volumes of this series

A B CALLEAR

British Transistor, Diode and Semiconductor Devices Data Annual, 1962–63

Edited by G W A Dummer and J Mackenzie Robertson Pp lv + 935 (London and New York Pergamon Press, 1962) 140*s* , 25 dollars

THIS volume collects together the data sheets on semiconductor devices issued by British manufacturers and by overseas firms with manufacturing facilities in the United Kingdom The advantages of such a volume over collections of manufacturers' data sheets are two-fold all the data are to be found compactly in one place, and the excellent indexing provided allows the device desired to be identified rapidly Devices are classified throughout in three groups transistors, diodes and (other) semiconductor devices Reference to devices can be made from either a list of application classifications or by manufacturers' type number Under the heading "Applications", transistors are divided into 17 classes, while diodes are listed according to order of peak inverse voltage and are also divided into eight application categories, other semiconductor devices are listed according to their nature—photoconductive / photovoltaic cells, silicon-controlled rectifiers, etc

Indexing by name of manufacturers has been made particularly useful by including a brief description of each device, including its physical nature, field of application, significant aspects of performance (for example, frequency range, voltage or power rating), and any feature of special note

The volume also includes a useful short introductory chapter giving a brief description of typical construction of semiconductor devices and their relevant properties, illustrated by diagrams showing physical configurations

The data sheets themselves are reproductions of those issued by the manufacturers concerned Their juxtaposition directs attention to considerable variation in the selection and presentation of data by different firms To have reduced the material to a consistent form and notation, however, would have been a well-nigh impossible task

A R BOOTHROYD

ON MAKING MUSIC

SUBSTANCE OF A FRIDAY EVENING DISCOURSE AT THE ROYAL INSTITUTION, LONDON, ON MAY 18

By Dr H LOWERY

Principal, South-West Essex Technical College and School of Art, London, E 17

Have you a Musical Ear?

THE vast growth in acoustical engineering which has arisen through the reproduction and recording of sounds has led to extensive research in the properties of the ear and the conditions of hearing Psychologists and physicists have both made outstanding contributions and have almost revolutionized the approach to the traditional acoustics Though space will not allow discussion of the extensive and complicated subject of what constitutes musical ability, some simple facts of hearing may be mentioned As is well known, the range of hearing is approximately 20–20,000 vibrations (or cycles) per second though most adults do not reach this upper limit Some individuals may have tonal gaps in this range, to deal with which 'acoustical spectacles' may have to be provided to cope with the deafness

This is a bare fact indicating that the aural instrument, perhaps aided, responds serviceably in the simplest possible way Music, however makes much more exacting demands It expects the ear to be capable of discriminating between very slight differences in pitch, and in intensity or loudness, from which we readily appreciate that the simple sensation of hearing is by itself not sufficient A mental judgment is involved Hence the popular term 'musical ear' is obviously only a half-truth

We have to realize that in music we are concerned not with individual notes and chords but with their relations with one another Thus notes are played together to form 'chords', or in sequence to form 'melody' It is important to remember that notes in music are never treated in isolation Even if a given note or chord is sounded by itself, the mind automatically relates it to aural images of previously heard sounds

The effect of any one chord depends on the chords which preceded it The study of the sequence or resolution of chords is, in actual fact, a very important part of musical theory called 'harmony', and though this study may reveal fashions based on temporary preferences for certain particular chordal sequences, nevertheless harmony as a subject is an aspect of musical education which cannot be neglected

Considerations of the above facts soon make it evident that the scientific and musical approaches to sound are quite different The physicist is content to study the means of production and reproduction of single sounds If he discusses the effect of sounds in combination he is still interested in the effect as a single phenomenon When combinations of sounds, namely, chords, are compared with one another and the effect of their sequence studied, we enter on the province of the musician

Pianoforte Tone

This difference in point of view is particularly well marked in considering the production of tones on the pianoforte

Some years ago certain American physicists (Hart, Fuller and Lusby) examined the tones produced by the pianoforte string using a cathode ray oscillograph It appeared that it did not matter whether the pianoforte key was depressed by dropping a brick on it, or pushing it down with the end of an umbrella, or allowing a tiny tot to try his hand, the general shape of the wave curve in each case seemed to be the same

There were folks who somewhat hastily jumped to the conclusion that this experiment had debunked all pianoforte teaching Pianists have long emphasized that there exists an almost infinite variety of 'touches' ranging from *legatissimo*, involving the closest binding of notes in succession, to *staccatissimo*, by which they imply the quickest release which can be made to the pianoforte key It is through the unique use of these touches by the master pianists that their personalities become manifest

In discussing this matter, physicists have emphasized that the only thing the pianist can control is the speed of depression of the piano key which in turn means that he is also controlling the speed at which the hammer strikes the strings with consequent changes of loudness All this happens before the key has reached the bottom of its fall To the pianist, this is not new information Piano teachers deprecate pressing the key into its bed, for they know that once the hammer has struck the string no further variation in tone is possible

It should be emphasized again that the physicist is satisfied when he can explain the mode of production of a single note whereas the musician is concerned with the effect that follows from the relatedness of notes to each other It is obvious from very elementary considerations that if the piano string is struck very forcibly, a loud tone is produced with a considerable overtone content, whereas if only feebly struck the higher overtones will scarcely be heard so that a difference in quality between the loud tone and the feeble one will be produced This difference between successive tones on the piano may be so slight as to elude the cathode ray oscillograph but yet may readily be picked up by the ear, which is itself an excessively sensitive instrument It is these subtle variations which the trained pianist is able to make through his fine control over the key action that constitute the life-blood of pianoforte playing They are vital and are charged with emotion in the effects they produce They enable him to impart dynamics to the music besides rendering the music meaningful through skilful phrasing True, the scientist may rightly pride himself on his objectiveness and regard himself as 'untemperamental' But the musician must be subjective in his outlook Tonal perception involves mental judgment This is subjective Music is an activity of the mind

Vibration of Strings

String instruments of the violin family play an important part in musical performance The laws of vibrations of strings are, of course, well known, particularly that which expresses the fact that the pitch of the note produced is inversely proportional to the length of the vibrating segment In the violin, for example, the player presses or stops the string against the finger-board at various points and so is able to alter the length of the vibrating segment to give the note he requires

Moreover, a musical sound is accompanied by overtones the frequencies of which are derived from the series of natural numbers By lightly touching a vibrating string at various points it is possible to isolate certain of these overtones and so make them more obvious

It is apt to direct attention to two simple but none the less fundamental experiments In the first we recall a fact of great importance in practical music, namely, that if two sources of sound are in unison and one of them is set in vibration, the other picks up these vibrations and responds 'sympathetically'

The second experiment was originally described in the *Transactions of the Royal Society*, in 1677, by Dr John Wallis, Cambridge mathematician, and a friend of Newton ("On the Trembling of Consonant Strings—a New Musical Discovery") The actual work was done independently by two young enthusiasts for the new experimental philosophy, namely, Mr William Noble of Merton College, and Mr Thomas Pigot of Wadham College, Oxford They made a string vibrate sympathetically in aliquot parts by sounding an adjoining string of different pitch Their early experiments were done on a lute They then constructed a special piece of apparatus consisting of strings stretched over a flat board and demonstrated nodes and anti-nodes during vibration with the use of paper riders This seems to have been the earliest use of the sonometer

In the technique of violin playing a special department is devoted to this production of overtones through lightly touching the strings at various points The tones produced in this way are known as harmonics

An amusing incident may be mentioned here involving the great Dr William Whewell, a former Master of Trinity College, Cambridge, and author of the first *History of the Inductive Sciences* One of his pupils was the Rev R H Haweis, who afterwards became rector of St George's, Hanover Square, London Haweis was a creditable performer on the violin and played solos regularly at Cambridge concerts At one of these he disported himself in a show piece by de Beriot, throwing off harmonics with the greatest of ease This led Whewell to remark with characteristic frankness "Mr Haweis, I have never held your scholarly attainments in high regard but how you produce those harmonic notes without resort to a foot-rule to sub-divide the violin strings leads me to take a new estimate of your capabilities"

The violin playing of Paganini has become legendary He undoubtedly made significant contributions to the technique of playing the instrument and evolved modes of production of violin tones which were new and startlingly effective

On December 9, 1831, Paganini performed in the ballroom of the Old Ship Hotel, Brighton—still commemorated by a plaque in the room This concert aroused particular interest because of the alleged excessive charge for tickets to hear "a mere foreigner" play the fiddle at a time when the country had so many needy poor Nevertheless, the concert was packed, and, as was usually the case when Paganini played, the audience was whipped into a frenzy

Mr Walker, an enthusiastic amateur, after hearing the concert, wrote to his friend, Mr Pringle, in Shrewsbury, to say that in spite of all criticisms the concert would have been worth ten times the charge to see this wizard play the violin in a way "that defied the very laws of nature" Mr Pringle waited two years to confirm his friend's opinion On August 15, 1833, Paganini gave a concert in the Golden Lion Hotel, Shrewsbury (commemorated by a plaque), whereon Mr Pringle wrote to Mr Walker "My Friend, you indeed spoke but moderately when you opined that Signor Paganini defied the very laws of nature This *maestro* is not a wizard defying the laws of nature, indeed, he is the very god that makes the laws of nature'

Here we have two testimonies that Paganini did something unexpected What is the explanation? It derives from the law which states that the pitches of the notes from vibrating strings are inversely proportional to the lengths of the vibrating segments The violinist normally obtains his high-pitched notes by shortening the vibrating segments obtained from pressing on the finger-board at points nearer the bridge But Paganini made extensive use of harmonics and touched the string at positions farther away from the bridge Hence he seemed to be defying the inverse law by doing the opposite of what was expected

Old Italian violins are greatly prized by players to-day, particularly those by Stradivarius, so much so that most modern violin makers have concentrated on copying the old masters An air of mystery seems to surround the subject Many have sought, without success, a so-called Stradivarius secret It has, for example, been attributed to the kind of varnish used or to the choice of wood from a certain district in the Alps with a favourable sunny aspect, or from the thicknesses of the plates The number of fine old instruments available is far short of world needs hence it is important that modern makers should be encouraged Time will, of course, add its own contribution to their work

I have recently had discussions with a present-day maker, Mr Ernest Cowell, formerly of Norwich and now of Basildon, Essex, who has done some original thinking on the making of violins He does not copy old instruments, but is able to take a piece of wood and mark it out from acoustical principles even to the final placing of the bridge and sound-post It is possible that Stradivarius himself proceeded on similar lines Mr Cowell, like Savart, the French scientist, who investigated the subject a hundred years ago, considers that if there is a Strad secret it probably lies in the form of the instrument As Mr Cowell says, Strad was "a better mathematician than he has been credited for"

Brass Instruments

It is interesting to note that musical education is now so far advanced in schools and colleges as virtually to have brought into being a new industry for the manufacture of brass and woodwind instruments In the forefront stands the English firm of Messrs Boosey and Hawkes, which exports to markets all over the world, their Edgware factory being the largest in Europe Besides practising high levels of traditional hand craftsmanship, it has also been successful in developing new methods of large-scale production involving thousands of instruments a year

If we examine a brass instrument such as a cornet, or trombone, or tuba, we realize that it has to have a tube-length comparable with that of the pipes for notes of similar pitch on the organ Thus, for a note three octaves below middle *C* the length required is about 16 ft For convenience to the player the size is made manageable by coiling the pipe Clearly this creates an immense difficulty in manufacture Messrs Boosey and Hawkes have developed a method of curving pipes into suitable forms by a hydraulic press served from a compressed air line at 80 lb /in ² The straight pipe is first bent roughly by hand around a suitable curve, which has the effect of collapsing it It is then inserted into a hydraulic former in which it is inflated to the correct shape

In spite of the use of mass-production methods, the final toning of both brass and woodwind instruments is checked and adjusted by trained musicians.

THE LARGE HOMOPOLAR GENERATOR AT CANBERRA

INITIAL TESTS

By J W BLAMEY, P O CARDEN, Dr L U HIBBARD, Dr E K INALL, R A MARSHALL
and Sir MARK OLIPHANT, K B.E , F R S

Research School of Physical Sciences, Australian National University, Canberra

THIS laboratory has been engaged for some time in the design and construction of a large homopolar generator[1] The generator was intended to provide a pulse of current, of roughly sinusoidal shape, into the orbital magnetic field coils of an ironless proton-synchrotron for 10 GeV , the peak current being 1 6 million amp , and the initial potential difference 800 V , while the stored energy at 900 r p m , in the two rotors, each weighing 40 tons, is 5×10^8 joules The current is collected from the rotors by continuous sheet jets of liquid metal (sodium–potassium alloy) impinging radially around the periphery of each steel disk at a radius of 69½ in , and vertically along the magnetic field (16,000 gauss) at a radius of 24 in The generator is filled with pure nitrogen at about atmospheric pressure

Fig 1 shows diagrammatically the arrangement used in these initial tests, which were designed to test the ability of the jets and machine to withstand the effects produced by drawing the full current The bottom rotor is clamped solidly in position The lower disk of the upper rotor is driven as a Faraday disk by a current from a rectifier, flowing radially between a set of four equally spaced jets of sodium–potassium, 2 mm in diameter, on a circle of radius 24 in , to four similar jets making contact with the periphery A driving current of 1,200 amp gave adequate acceleration to the limited rotational speeds used in the tests The pulse of current was drawn from the upper disk only, and was conveyed to an electrolytic load by a system of aluminium conductors The load was an arrangement of interleaved steel plates, spaced about ¾ in apart, which could be immersed in a tank of sodium hydroxide solution when this was raised hydraulically from below

The admission of sodium–potassium alloy to the current-collecting jets on the top disk, and the variation in the resistance of the electrolytic load, were programmed to give the required pulse shape Fig. 2 shows how the flow of alloy through a jet varied with time in relation to a current pulse The jets were established before the circuit was closed by entry of the caustic soda solution between the plates of the electrolytic load

A series of pulses of up to 10^6 amp , with a half-second width at half current, has been delivered to the load at potential differences up to 66 V The electrical energy agrees with the change in mechanical energy, within the errors of observation, so that the internal losses are small

It was intended to observe several pulses with peak current of about 10^6 amp before proceeding to the current of $1 6 \times 10^6$ amp for which the generator has been designed However on the second such pulse, the unbalanced electromagnetic forces between the plate assemblies of the electrolytic load, due to uneven separations or current distribution, pushed these into contact, so that the current rose sharply to a peak of $1 8 \times 10^6$ amp as shown in Fig 2 The jets, running at less than full flow, appeared to have carried this current satisfactorily, and measured deflexions of the magnet and the jet structure were

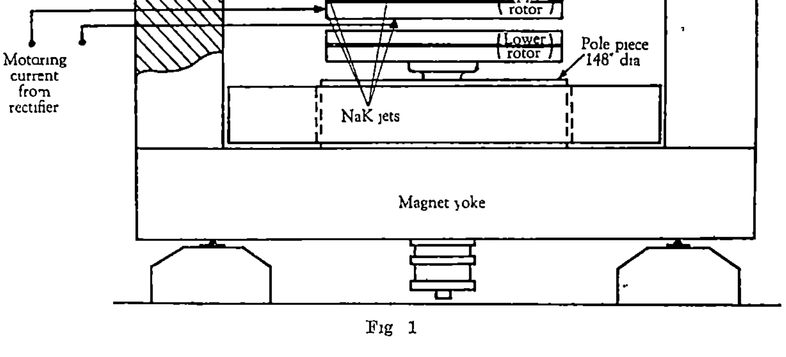

Fig 1

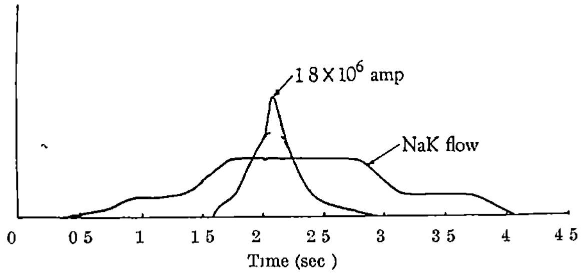

Fig 2

within the tolerances allowed The current reacts on the magnet with a torque of 2 000 ft -tons

These results are very encouraging, indicating that the design analysis is not seriously in error, and that the various assumptions made about the behaviour of the current-carrying jets are justified It is now reasonable to believe that the complete generator will behave as planned A stored energy of 5 × 10^8 joules will then be available for a wide variety of physical experiments, including the production of large magnetic fields over considerable volumes, such as are desirable for work in plasma physics

There remain many questions to which answers must be obtained before all aspects of operation are understood and the generator is working reliably at full power Solutions to many of these problems have been worked out Continuation of the present series of tests will yield information about the validity of these solutions, and will inevitably indicate other problems which have not yet been envisaged However, progress should now be rapid

The tests have provided some interesting observations of the behaviour of liquid conductors moving in a magnetic field These are in general accord with what would be expected from simple magnetohydrodynamic considerations The liquid metal exhibited a high degree of stability and tended to remain continuous, rather than to break up into streamers and drops Further work is planned on these phenomena

We thank Mr D B Shenton of the Atomic Energy Research Establishment, Harwell, who was the first research engineer on the project and to whom much of the basic constructional design is due, Dr D Robertson, who has given assistance and advice, and Mr H Johnson, who was an active member of the team for some years

FUNCTION, DEVELOPMENT AND EVOLUTION OF THE NUCLEOLUS

By Dr J L. SIRLIN* and Dr J JACOB†
Institute of Animal Genetics, Edinburgh 9

OUR present work on the nucleolus suggests certain conclusions about its function, development and evolution which may serve as guides to future research This work has involved the examination of autoradiographs after treatment of the cells with inhibitors of nucleic acid metabolism, and also investigations with the electron microscope Both these techniques have a high topographical resolution, but, in different degrees, allow of only less-precise biochemical interpretations

Nucleoli are already known to contain transfer RNA[1,2], messenger RNA[3], and a nondescript high-molecular weight RNA[4] It may be assumed on general principles that the messenger RNA originates in the chromosomes In our opinion the presence of DNA in the fully grown nucleolus has not been rigorously demonstrated, except for that present in the nucleolar organizer

Function of the Nucleolus

The system used for autoradiography is the mature chironomid salivary gland cell[1] The nucleolus has a central organizer and RNA is synthesized in close proximity to, but not actually in, this organizer, it then flows centrifugally, the clearance time being about 2 hr

Actinomycin blocks primer DNA but not primer RNA in the RNA polymerase system and in living cells[5], and as used in our system it would presumably not totally block primer RNA The effect is on the DNA and not on the enzyme (Kornberg's DNA polymerase system is much less affected) If our system is treated with actinomycin and the cells then offered labelled nucleosides, three classes of inhibited nuclei are found[6] (1) nuclei in which uptake into RNA is partially inhibited in the chromosomes and completely inhibited in the nucleolus, (2) completely inhibited but healthy nuclei, (3) completely inhibited nuclei with damaged chromosomes and destroyed nucleoli The complete inhibition of nucleolar RNA turnover seen in class 1 indicates that this turnover must ultimately be primed by DNA, and since the nucleolus contains no DNA of its own (except for the organizer, in which, however, RNA does not turn over[1]) this must be chromosomal DNA The effect of actinomycin therefore indicates that the nucleolus requires a contribution of DNA primed RNA derived from the chromosomes Once this RNA has reached the nucleolus we refer to it as the 'extrinsic' nucleolar RNA

TRB (4,5,6-trichloro-β-D-ribofuranosyl-benzimidazole) is a general RNA inhibitor[7] When TRB acts on our cells at the same time that tracer is offered it has no effect When it acts prior to the offer of tracer it results in three classes of inhibited nuclei[6] (1) nuclei completely inhibited, (2) nuclei with completely inhibited uptake in chromosomal RNA and with uptake in nucleolar RNA strictly confined to the vicinity of the organizer (a phenomenon which we call blockage), (3) nuclei with blocked nucleolar RNA but little or no inhibition of chromosomal RNA The blockage of nucleolar RNA is overcome during chase in the absence of TRB, the nucleolar RNA clearing out at a slowed-down rate while the chromosomal RNA does so at a normal rate A similar blockage is caused in isolated thymus nuclei by the related compound DRB[8]

* Agricultural Research Council Unit of Animal Genetics
† British Empire Cancer Campaign

The class 2 nuclei following TRB indicate that some turnover of nucleolar RNA continues in the vicinity of the organizer, even after all chromosomal RNA synthesis is inhibited, and the supply of extrinsic nucleolar RNA shut off. There must therefore be an innate RNA turnover in the nucleolus which produces 'intrinsic' nucleolar RNA in addition to the extrinsic RNA mentioned above. This same conclusion had been previously reached on kinetic grounds[1], and it is known that there is a net RNA synthesis in the nucleolus[9]. Since even the intrinsic turnover is totally abolished by actinomycin it must ultimately depend on a DNA primer. We take it that this primer is the chromosomal DNA and that it produces the extrinsic nucleolar RNA which then, after arriving at the nucleolus, acts as primer for the intrinsic nucleolar RNA synthesis. The nucleolar RNA produced in this way might be either an exact self-primed replication of the extrinsic RNA or the synthesis of a somewhat modified RNA primed by extrinsic RNA.

The extrinsic RNA contributed to the nucleolus from the chromosomes is almost certainly messenger RNA, the presence of which has been demonstrated in the nucleolus[3]. Further support for the demonstration that messenger RNA occurs in the nucleolus comes from the nucleolar inhibition caused by 5-fluorouracil[10] and azaguanine[11], since both these analogues enter into RNA and adulterate messenger[12] as well as other RNA's.

Direct evidence of a free messenger RNA of chromosomal origin can be seen in class 3 of TRB-nuclei[6]. In these the nucleolar RNA is blocked but uptake continues into the chromosomes and there is also present in the nuclear sap a quantity of labelled RNA corresponding approximately to the level of activity remaining in the chromosomes, this free RNA is of high specific activity, that is, is newly made. There is other evidence[10] suggesting that messenger RNA normally passes from the chromosomes to the nucleolus through the nuclear sap, we have attempted to trace with autoradiography any RNA flow there might be along the nucleolar chromosome towards the nucleolus, and if this occurs it should be detectable in chase experiments, but we have been unable to find evidence of it (although there is a flow of particles along the chromosome for distances of a few bands during the early stages of nucleolus formation (see next section)).

One can conclude from these observations that there is an intrinsic nucleolar RNA synthesis which is primed by extrinsic RNA (probably messenger RNA) and which results in the production of an increased quantity of RNA either identical with, or slightly modified from, the extrinsic supply. The most general statement about the function of the nucleolus, therefore, is that it acts as an amplifier of the synthesis of chromosomal RNA.

Development of the Nucleolus

The nucleolus is initially a chromosomal product (cf. ref. 9). In most interphase nuclei prenucleolar bodies arise from the chromosomes and eventually become organized into a single nucleolus. Many nuclei which contain a single nucleolus often also contain small accessory nucleoli. Having regard to all the many different forms of nucleolus found in different cells it seems most reasonable to consider the single well-defined large nucleoli of certain cells as being the organized form which may be taken by a more generally occurring nucleolar substance[9].

The formation of this nucleolar substance has been followed by electron microscopy in the mature sciarid nucleus[13], in which nucleolar organizers are lacking. In the salivary chromosomes numerous small 'elementary nucleoli' form at certain bands (not at interbands). These gradually develop into small nucleoli, which behave metabolically[14] like the larger nucleoli of chironomids, except that RNA is synthesized in their periphery and flows centripetally, whereas in the chironomid it is synthesized centrally and flows centrifugally. The first sign seen of the formation of these nucleolar elements is the appearance of ribonucleoprotein particles of about 100 Å clustered around points in the chromosome fibrils at the bands. These clusters of particles grow by apposition of new particles, fuse into larger masses, and gradually move to the periphery of the band. When a band (pre-puff ?) contains larger granules of about 400 Å diameter these are also added to the nucleolus at that band, if the band does not contain these granules, the nucleolus does not have them either. There are often thick layers of particles on the chromosome surface and these become added to the nucleolar masses as they are extruded, and sometimes connect together several of them coming from nearby bands. Finally, the nucleolar masses lose contact with the chromosomes and become small free nucleoli. During their growth the original chromosomal fibrils, around which the particles were initially clustered, become gradually no longer recognizable.

In the chironomid nucleus and other nuclei containing a single nucleolus, the initial stages of nucleolar formation are probably the same as in the sciarid just described, but they are followed by a later stage at which the elementary nucleoli are brought together into a single body by the nucleolus organizer. This organizer is a gene, and it is clear that it is to be regarded as an evolutionary acquisition by certain forms. When nuclei which normally possess organizers lose them by deletion, they revert to the primitive condition of the sciarid, showing many scattered small nucleoli, both in polytene nuclei and in interphase nuclei (such a condition is eventually but not immediately lethal). The primitive condition therefore seems to be that each gene makes its own elementary nucleolus if it needs it, as many of them seem to do. Something similar still happens in evolved nuclei in the case of differentiating puffs in polytene nuclei and in interphase nuclei which produce accessory nucleoli.

Evolution of Nucleolar Function

We came to the conclusion above that the extrinsic nucleolar RNA which acts as a primer for the intrinsic nucleolar RNA synthesis is messenger RNA derived from the chromosomes. This has been proposed before[15], but we have been able to provide firmer biochemical evidence in support of it.

As stated above, we have directly observed free messenger in the nuclear sap. We can ask if all messenger normally passes through the nucleolus. Observation shows that it need not necessarily do so, since when the nucleolus is blocked with TRB the messenger can be seen not only in the nuclear sap but also in the cytoplasm, where it first accumulates in the neighbourhood of the nuclear envelope, this passage to cytoplasm independently of the nucleolus was also inferred kinetically[16] in normal cells. It is perhaps possible to regard this messenger as having been formed in residual elementary nucleoli within the chromosomes But if we adopt this view, the constituent particles in the elementary nucleoli would in fact amount to no more than the genes themselves plus the messenger RNA which they are manufacturing, and there would be no reason to suppose that the messenger had passed through any specifically nucleolar phase

We may then proceed to ask whether there is *some* messenger which has to pass through the nucleolus, even though much of it need not do so This question cannot be so simply answered from mere observation, although the effect of the nucleolar inhibition by azaguanine on cytoplasmic protein[11] might be held to suggest that the inhibition of the nucleolus leads to a loss of essential cytoplasmic messenger It must also be remembered that some messenger may be used internally for syntheses in the nucleolus itself In its general form, however, the question at issue raises the whole problem of whether the function of the nucleolus is merely that of amplification, or whether it brings about necessary modifications of the chromosomal RNA, that is to say, is the nucleolus in principle redundant or indispensable ? The idea that it is redundant is an old one, recently formalized[9] Its main advantage is that it does not attribute an essential (that is, specificity conferring) function to a structure which in effect lacks DNA The alternative would be to suppose that the nucleolar RNA has a genetic continuity which enables it to function like DNA, but the evidence[9] is rather against this continuity Moreover, intrinsic nucleolar turnover size is large compared with that of single genes, and may be very considerable in differentiating cells (referring here to what was called 'independent nucleolar RNA" in ref 9), and therefore appears suitable to meet the demands for amplification of particular messengers A lack of this amplification may be the reason why lower organisms without nucleoli never attain the multicellular complexity seen in more evolved organisms with nucleoli Such an amplification process would give the nucleolus a rate-limiting function[17]

The alternative hypothesis to amplification, that is, modification of messenger at the nucleolus, still deserves consideration, although we have no positive evidence to support it There is the possibility that the modification involves degradation The fact that messenger can be converted to ribosomal RNA after rearrangement of nucleotides[18] shows that messenger can, in fact, be modified Some modification may be necessary for the coding triplets in messenger RNA which are known to contain relatively rather too much of uracil[19] Since the turnover of uridylic acid has been reported as being higher in nucleolar RNA than in nuclear RNA[20], this nucleolar turnover might suggest a modification of messenger to that end Similarly, the first synthesis of hæmoglobin in the cell was detected at the nucleolus[21], and this might indicate that the messengers are somehow first made functional in the nucleolus, although, since in this case also the chromosomes apparently later synthesize the protein, the earlier nucleolar synthesis could simply be due to the amplification rather than to the adaptation of messengers Modification of messenger may also be the mode of formation of transfer RNA[9] which is ultimately DNA primed[22] as nucleolar RNA itself is If transfer RNA is salvaged degraded messenger (rather than degraded ribosomal RNA as in ref 23), then the problem of accounting for the conferment of specificity to transfer RNA at the nucleolus becomes less The modification might include the appearance of the unusual bases of transfer RNA, even if it is complementarily replicated on messenger It is perhaps suggestive that a series of types of RNA which depart increasingly from the DNA type of base composition, that is, messenger–transfer–ribosomal, are located at correspondingly increasing distances from the genes in the series of structures chromosome–nucleolus–ribosome

What we now know of nucleolar evolution also suggests that the nucleolus is concerned with the function of messenger RNA We take it that the sciarid condition, although it can possibly be derived from the chironomid condition by a single gene mutation leading to the loss of the organizer, represents the primitive situation In this, elementary nucleoli are associated with single genes The evolved consolidated nucleolus is associated with the whole genome In the primitive nucleus, gene DNA primes the synthesis of messenger RNA, which may thereafter be amplified by self-priming in the multiplying elementary nucleolar particles (primer RNA is associated with particles also in the enzyme system[5]) The resulting elementary nucleoli are then gene products Any DNA which becomes trapped within these nucleoli during their formation later becomes waste or disappears In more highly evolved nuclei the elementary nucleoli (or prenucleolar bodies) from many genes become consolidated into a single nucleolus, presumably this saves reduplication of energy-consuming processes in the multiple elementary nucleoli, and assists the co-ordination of the output of messengers, etc The consolidation of the single nucleolus is the function of a mutated gene—the organizer—which, however takes no part in the synthesis of the nucleolar RNA although remnants of its DNA may be trapped inside the nucleolus It is, however, the messenger RNA, not the organizer DNA, which primes the intrinsic nucleolar RNA synthesis, itself becoming amplified and perhaps modified in the process It i this fact, which emerges from the effect of RNA inhibitors on the nucleolus, which makes it possible to regard the dispersed nucleoli of the sciarid and the consolidated nucleolus of the chironomid as two stages in the evolution of structures fulfilling the same cellular function

In the course of nucleolar evolution some changes in the topography of turnover have occurred The region of the nucleolus which actually synthesize the intrinsic RNA is the dense particulate region[14,24] This can be located either centrally or peripherally depending on whether, during the formation of th nucleolus, the organizer is centrally located as i chironomids or lies at one side of the nucleolus as i Drosophilids and many other metazoa When th organizer and the dense particulate region lie centrally, the RNA moves centrifugally When the dens particulate region is peripheral the RNA move centripetally, but in this case it is not related to th particular portion of the surface of the nucleolus a which the organizer is externally located, the sciar nucleolus without organizer shows the same pattern Whatever the pattern, the intrinsic RNA synthesize in the dense particulate region eventually fills th whole nucleolus As to the mechanism by whic the messenger RNA reaches the nucleolus, it i not yet quite clear whether this is by random collision after free diffusion through the nuclea sap, or whether there is any directed movemen of messenger towards the nucleolus The latte possibility is perhaps suggested by the kinetics o the orthophosphate pool[25] It also seems possibl that the nucleolus-associated chromatin of interphas nuclei may be a feeder of messenger to the nucleolus However, the fully formed nucleolus is usually quite large enough for it to seem plausible that the free diffusion of messenger would be a sufficient mechanism

As we see it, the interpretation which has been presented has several advantages It explains under a single scheme both nucleolar development and function for virtually any form which nucleoli may take, even down to presumable ultrastructural (elementary) nucleoli in lower cells It does so within a framework where all necessary genes participate Finally having regard to the function of messenger RNA, self-priming of messenger as the basis of nucleolar function seems to correspond well with the essentially auxiliary, although in the long run indispensable, general nature of nucleolar function[9]

It remains to say a word about nucleolar protein In both the primitive dispersed nucleoli, and in the more evolved consolidated nucleoli, the protein turnover occurs uniformly throughout the whole body of the nucleolus and shows no directional characteristics In adult cells it occurs mainly during the period of nucleolar growth and is only slight in the fully formed nucleolus This suggests that the protein synthesis is mainly an aspect of nucleolar growth, and not the production of something like RNA which is contributed to the rest of the cell In evolved nucleoli some protein could come to the nucleolus in the prenucleolar bodies, and it was actually shown that some of the protein comes from the nucleolus of the previous cell cycle[26] On the other hand, it might well be that the main synthetic function of the organizer could be the early production of an organizing nucleolar protein[24] This is perhaps suggested by the topographical relationships between the organizer and the dense particulate region mentioned above It should also be noted that in cleanly isolated nucleoli there is only one major protein[27] It has been suggested that the nucleolus synthesizes ribosomal protein[28] If so, this protein would presumably have to be made in the many dispersed elementary nucleoli in the less-evolved stage This possibility cannot be ruled out, but, since ribosomal protein has a similar overall composition in all species examined, the suggestion that many different genes all make essentially the same ribosomal protein does not appear to us very attractive Our view[24] is that the nucleolus (and possibly the nucleus as a whole) essentially contributes free informational RNA's and does not contribute protein, which is made outside the nucleus and possibly by the ribosomes themselves Evidence for this comes from the free state of messenger[12] and, possibly, from ribosome reorganization during regeneration[24]

We thank Prof C H Waddington for help in preparing the manuscript

THE LOWER ARCHEGONIATE PLANTS

OVER the years the Linnean Society of London has had many important meetings and discussions to its credit The recent symposium on "The Growth and Development of the Lower Archegoniate Plants", held in the Society's rooms during April 5–6, had, however, the unique distinction, as the president, Prof T M Harris, stated in his opening remarks, of being the first truly international symposium ever arranged by the Society In addition to British representatives, the speakers included botanists from Canada, the United States, France, Germany and Finland, and, in all, sixteen papers were read About one hundred people attended each of the four sessions In passing, it may perhaps be noted that a group of this size proved admirable for the progressive development of full and friendly discussions

In opening the first session (over which Prof Harris presided) on the gametophyte, Mr P R Bell (University College, London), to whom much credit for arranging the symposium is due, referred to the value of ferns and mosses for studies of growth, development and differentiation He indicated that classical problems of long standing concerning the differences between the alternating phases of the life-cycle might perhaps be solved by the application of new techniques, and he affirmed that principles of cellular biology based on the lower archegoniate plants could have important applications to higher plants Prof H Mohr (Botanisches Institut, University of Freiburg, West Germany) then submitted observations on the influence of visible radiation on the germination of spores of archegoniate plants, in particular of *Dryopteris filix-mas*, *Funaria hygrometrica* and *Sphaerocarpus* sp, and on protonemal growth These and other investigations indicate clearly the importance of light and of photoreactive systems in growth and morphogenesis Spore germination in *F hygrometrica*, for example, is controlled by light, though the processes involved are complex The first stage of germination, involving the uptake of water, enlargement, rupture of the exospore and conspicuous greening of the plastids, can occur in darkness in some of the spores of a population The results so far obtained indicate that the control of this stage is mediated by the phytochrome system The second stage, which includes the outgrowth of the rhizoid and/or chloronema, is also controlled by light, photosynthesis being involved The spores of *Sphaerocarpus* are obligate light germinators, at least two photoreactive systems being involved

Since germination can be induced by both blue and far-red radiation, it is tentatively assumed that there is a promotive photoreactive system identical with the blue, far-red reaction system (the so-called 'high energy reaction of photomorphogenesis') The inhibiting reaction system, which is particularly effective with longer daily periods of irradiation, may be identical with the phytochrome system

In *Dryopteris filix-mas*, the relative and absolute protein contents of blue-grown prothalli increase much more than do the protein contents of the corresponding red-grown filaments (protonemata), even when the increase in dry weight is about the same under both light conditions After a transient increase the relative protein content remains constant in darkness and in red light, whereas in blue light the relative protein content increases steadily, at least during the experimental period If red-grown protonemata are placed under blue light and blue-grown prothalli under red light, rapid shifts in the relative protein contents are observed, indicating that, in a gametophyte, the protein content is actively brought to a certain level determined by light wave-length It thus appears that the increased rate of protein synthesis in blue light is intimately connected with the related critical developmental changes It is probable that photomorphogenetic light reactions determine into which metabolic pathways the primary products of photosynthesis are channelled In the plants under consideration, a photoreactive system which depends on blue light apparently directs this flow of metabolites primarily in the direction of protein synthesis

Prof A Vaarama (in collaboration with Nina Tarén, University of Turku, Finland) gave an account of the synergism of calcium and certain growth substances in the germination and protonemal growth of mosses, based on their experimental studies of certain lithophytic and non-lithophytic calcicolous species and a calciphobous species Among other observations, gibberellic acid inhibited protonemal growth in all the calcicolous species tested, but promoted growth in *Dicranella cerviculata*, a calciphobe

Prof M Bopp (Botanisches Institut, University of Freiburg, West Germany) discussed differentiation in moss protonemata and the factors controlling bud formation in them During the development of the protonema of *Fumaria hygrometrica*, two different substances diffuse into the substrate In the chloronema a heat-labile, growth-promoting substance is formed, in the caulonema, after about ten days, a heat-stable substance, soluble in amyl alcohol, is formed This substance functions as a growth inhibitor Both substances affect bud formation, which is at an optimum only when a certain balance between them exists This bud-inducing effect is fundamentally different from that due to kinetin, in that the latter only functions as an additional factor in promoting bud formation Kinetin is regarded as an agent which creates centres of activity toward which morphogenetic substances are drawn This view is supported by the facts that kinetin cannot be transported and therefore has no 'after-effect' and that it functions only when it penetrates a caulonema cell It converts every caulonema cell into a 'reaction cell' The opening session was completed by a contribution by three French workers, Messrs Kofler, Dutel and Nurit, on variations in the geotropic sensitivity of germinating *Funaria* spores in response to external factors such as light, and to applied growth substances, glucose, etc (This paper was read by Dr E Lodge)

The second session (under the chairmanship of Prof C W Wardlaw, University of Manchester) was mainly devoted to factors which affect the formation of antheridia Dr U Naf (Rockefeller Institute, New York) dealt with an antheridium-inducing effect of a specific substance which is apparently common to many polypodiaceous ferns, though it is inactive when applied to some Schizaeaceae, Osmundaceae and Cyatheaceae

The prothalli of *Onoclea sensibilis* respond to the active substances at an early stage of development but become incompetent to respond to it soon after they attain the adult heart-shape This loss of sensitivity occurs within less than two days Once they have become insensitive, prothalli fail to respond to the active substance even if they are supplied with very high concentrations, for example, 15,000 times higher than that which is sufficient to bring about a response in prothalli just two days younger Surgical studies by Dopp have shown that the meristem of the maturing prothallus begins to form a substance to which the loss of sensitivity can be attributed Dr Naf suggested that the antheridial factor acts by modifying a situation which blocks or inhibits antheridium formation In the course of a lively and entertaining discussion of this paper—to give one indication of the mood of the symposium—it emerged that the responses of antheridia in the common bracken, *Pteridium aquilinum*, were considerably different on the two sides of the Atlantic—varietal effects being no doubt involved

Dr D Wilkie (University College, London) then varied the general tenor of the session by giving an account of a genetical analysis of bracken (*Pteridium aquilinum*) prothalli In the course of this work, based on the pure culture of single spores, he frequently observed a form of prothallus lacking a meristem Actually, some 20 per cent of the spores yielded these small, ameristic prothalli, they bore antheridia and most of them usually reverted to normal forms The genetical properties of these variant forms were investigated by methods involving cross- and self-fertilization analysis A genetic analysis of the spores from the resulting sporophytes showed that control of the ameristic character could not be directly attributed to the action of nuclear genes Accordingly, a hypothesis of heritable cytoplasmic units was advanced to explain the results

The session was concluded by a paper from Prof L Bauer (Botanisches Institut, University of Tubingen, West Germany) on his experiments on the stabilizing of the male sexual tendency in mosses, *Splachnum* sp , that is, by the repression or exclusion of the female tendency by exposing plants to certain external conditions The persisting modifications which he obtained were attributed to cytoplasmic factors

In the third session (under the chairmanship of Prof L J Audus, University of London) the speakers were mainly concerned with the further differentiation of the protonema and prothallus and their products, especially as it related to the sporogonium in mosses and the ovum and young embryo in ferns Prof Bauer made a very interesting contribution on the physiology and organization of sporogonium differentiation in mosses He demonstrated that if different regions, apical, sub-apical and maturing, of the distal part of the young needle-like sporophyte were isolated and cultured, they typically gave rise to different morphological entities The more distal segments were capable of regenerative growth and eventually gave rise to sporogonia, but the more proximal maturing segments had apparently lost permanently some of their initial inherent potency and did not give rise to sporogonia when cultured under the same conditions as the other segments This observation in mosses appears to be in general accord with contemporary cytogenetical conclusions based on work in other groups

Mr P R Bell (University College, London) then gave an account of recent work on the cytochemical and ultrastructural peculiarities of the unfertilized egg in *Pteridium aquilinum* His lecture was illustrated by some excellent electron micrographs which not only shed new light on a classical botanical topic but also on fine-structural features of the nucleus and cytoplasm Critical observations on staining and cytochemistry were followed by an account of some novel observations on the nucleus and cytoplasm as disclosed by electron microscopy As the egg matures the nucleus appears to evaginate into the cytoplasm and there is evidence that, in the formation of the egg, the plastids and mitochondria derived from those of the gametophyte degenerate The mature egg, in fact, contains a new set of mitochondria, the evidence so far obtained from this material suggesting that they may be formed with the direct participation of the nucleus Although it has not yet been possible to correlate the peculiar cytochemistry of the egg with its unique ultrastructure, Mr Bell suggested that the evidence now accumulating admitted of the interpretation that the mature egg has a cytoplasm which is transformed under the influence of the nucleus, and this he considered may be responsible for the differences in complexity of the morphological configuration generated by the spore and the zygote

Dr A E De Maggio (Rutgers University, New Jersey) introduced the theme of the developing sporophyte by giving an account of morphogenetic factors which affect the development of the fern embryo In particular, he illustrated and discussed the effect of the physical restraint which may be exercised on the developing zygote by the archegonial wall and adjacent gametophyte tissues, and the effects of nutritional factors His surgical experiments showed that the early, complete removal of the natural, restrictive limitations imposed on the zygote and growing embryo seriously affects the potentiality of the young sporophyte for three-dimensional growth and normal sporophyte production Whether this single modification, which leads to what looks like a reversal of the regular phases in the alternation of generations, results in a loss of control over the planes of cell division, as previously suggested, or deprives the embryo of essential growth substances necessary for orderly sporophyte formation, remains to be seen In the species studied it is known that changes in carbohydrate nutrition do not account for permanent alterations in the morphological form Accordingly, the possibility cannot be overlooked that nutritional and hormonal interactions can give rise to changes in embryo development of such a magnitude as to suggest that these substances exert considerable control in determining morphological levels of development

These explorations of factors in the early embryogenesis in ferns were taken a stage further by Dr M Ward (Glenville State College, West Virginia), who discussed developmental patterns in adventitious, that is, non-sexual, sporophytes of *Phlebodium aureum* Such sporophytes are regularly formed when petiole and rhizome segments are grown in various culture media Gametophytic plants regularly develop from petiole segments but sporophytic plants are less common On rhizome sections in culture, sporophytic and gametophytic forms occur at random and often adjacent to each other. Apogamous sporophytes thus formed tend to give rise to secondary apogamous sporophytes on their own leaves In this fern, apogamous sporophytes are also regularly formed on the normal gametophyte under appropriate cultural conditions

The genetic constitution of these apogamous and aposporous forms has not yet been established Certain problems incident to the classical cycle of alternation of generations are indicated by the occurrence of these adventitious plants This session was concluded by an outline account of leaf regeneration in *Adiantum pedatum* given by Dr G Morel (Institute of Plant Physiology, Versailles) Since, in this fern species, juvenile leaves regenerate gametophytes, whereas adult leaves regenerate sporophytes, it may be inferred that during the process of ageing the factor controlling gametophyte formation, still present in juvenile leaves, tends to be lost If this be accepted, the problem is to ascertain how the same nucleus controls the development of these very different morphological entities—the small cordate laminæ with sex organs, and the sporophytic plant with roots and spore-bearing leaves, respectively In each, the information coded in the chromosomes should be the same but, nevertheless, the resulting organisms show marked differences in their morphology

The fourth and final session was held under the chairmanship of Dr C R Metcalfe (Royal Botanical Gardens, Kew) botanical secretary to the Linnean Society, who also had an important share in the arrangement of the symposium In an account of apical organization and allometric growth in ferns, Prof C W Wardlaw illustrated, by reference to a number of common British and some exotic ferns, that the main organizational features of the developing sporophyte of any particular fern and much of the morphological diversity in ferns in general can be referred (1) to the inception of a characteristic primary pattern of organs in the apical meristems of shoot and leaves, and (2) to various elaborations of these patterns by differential or allometric growth in the sub-apical and maturing regions

Factors of various kinds, genetical, nutritional, correlative and environmental, may, in different instances, affect the primary pattern and the nature of differential growth Accordingly, the view was advanced that the phenomena of organization in plants lend themselves to analytical and experimental investigation, but synthesis is evidently an essential part of the task

Dr T A Steeves (University of Saskatchewan) then contributed a detailed analysis of the growth and morphogenesis of the leaf of *Osmunda cinnamomea,* dealing first with the inception and development of the circinately-coiled primordium and of the maturing but still rolled leaf, and then with the further physiological activities which result in the uncoiling of the more or less adult leaf in spring Particular attention was given to the relative roles of cell division and cell elongation in the ground tissue of the leaf rachis throughout development The coiled condition of the rachis in the crozier was interpreted as the result of more cell division abaxially than adaxially during its formation, and uncoiling depends on the equalizing of cell numbers by cell division late in leaf development Cell elongation in *O cinnamomea,* except in the leaf base, is delayed until the fifth growing season, at which time it extends acropetally along the rachis Leaf elongation in several ferns depends on diffusible auxin, probably indolylacetic acid, from the pinnæ Leaf primordia, after being determined, can complete their development in isolation in sterile nutrient culture, indicating that the essential features of leaf formation are regulated within the organ itself The small size of cultured leaves is the result of diminished cell division in the rachis and appears to have a nutritional basis

Finally, in this session, Dr A Allsopp (University of Manchester) summarized and illustrated his many experimental investigations of morphogenesis in *Marsilea* spp, using aseptic culture technique Special attention was given to the effects of nutritional factors and growth-regulating substances in heteroblastic development and other organizational features, and to the physiological conditions which determine the characteristic features of land and water forms He concluded that the changes in leaf segmentation of *Marsilea,* or heteroblastic development are correlated with changes in the size of the apical meristematic regions of the shoot, which in turn are influenced by the nutritional status of the plant On the other hand, the differences between land and water forms are probably due to differences in the available concentration of dissolved carbohydrates in the growing parts

When I reflect on the symposium as a whole, my thoughts naturally turn to Hofmeister, Goebel, Campbell, Bower and Lang, and to the many other distinguished botanists of past times who contributed so much to our knowledge of the growth and morphology of archegoniate plants, and, not least, who were so profoundly interested in the causes underlying their singularly unlike alternating generations Had the shades of those eminent ones lingered awhile on this occasion, they might well have been stirred to surprise and wonder at the interest these plants and their problems still command, and, like myself, at the end of the meeting, they might perhaps have entertained the optimistic view that, although we evidently still have a very long way to go, we are at length coming within tangible distance of a more factual interpretation of some aspects of the growth morphology and life-cycle of these enigmatic and fascinating plants Accordingly, this is a suitable place to express the appreciation of all who participated in these sessions to the president and officers of the Linnean Society for arranging the symposium, and to the British Council and the International Union of Biological Sciences for very substantial financial assistance, without which, indeed, the symposium could not have been held

The papers contributed will be published collectively as a number of the *Journal of the Linnean Society* as soon as possible and this may be obtained from the Society C W Wardlaw

OBITUARIES

Dr L G G Warne

The University of Manchester has lost a valued member of staff in the sudden death of Leslie Gordon Glynn Warne on May 3, aged fifty-three years He had suffered a severe coronary thrombosis in 1955, which slowed his movements somewhat, he was well aware of a possible fatal recurrence, but he retained full mental vigour, wonderful personal equanimity, and continued his university activities as senior lecturer in horticulture and assistant director of the Experimental Grounds Actually, he was engaged on field work at the experimental grounds of the University, Jodrell Bank, Cheshire, when he collapsed

Warne was born at Faringdon, Berks, on June 25, 1908 On leaving St George's Secondary School, Bristol, he was employed for three years in investigational work in the laboratory of Messrs H J Packer and Co, Ltd, cocoa and chocolate manufacturers In 1928 he entered the University of Bristol, and in 1932 he graduated with first-class honours in botany In 1933 he was awarded M Sc and in 1936 Ph D He joined the staff of the University of Manchester in 1934 as assistant lecturer in botany, served the Department in many ways and was appointed senior lecturer in horticulture in 1948 This is an endowed post, the aim of which is to help gardeners and others to secure adequate scientific and professional training and to encourage horticulture in the region Warne had a considerable share in organizing the Experimental Grounds and evening classes in botany and horticulture in this connexion Indeed, his gifts as an organizer and as a practical gardener not only equipped him for this work and brought him success, but were also a great asset to the Department

In 1953 the University granted him three years leave of absence to occupy the chair of botany at Karachi, Pakistan There his varied ability again bore fruit, and his keenness and energy enabled him to acquaint himself with the work of other institutes in Pakistan and India, and to become familiar with tropical vegetation and agriculture.

During his earlier period in Manchester, Warne had complete responsibility for the degree course in plant physiology for about twelve sessions He also taught medical (1st M B) and dental students for several sessions, and served on various university committees His outside activities involved him in active membership of learned societies and of examining bodies He had a large number of published papers to his credit and was jointly responsible for the revision of Lowson's *Text-book of Botany* for use in Britain and also for India, Pakistan and Ceylon He was also joint author of a *Practical Botany* for home use, and one for use in tropical countries

In 1941 Warne married Miss M M Walker, whom he had met some years before at Long Ashton, and who was a lecturer at Swanley Horticultural College, Kent He is survived by his wife and three daughters Both in the Botany Department and more generally in the University he will be greatly missed as an unusually genial, even-tempered and helpful colleague

W O HOWARTH
C W WARDLAW

Dr T U Matthew

DR T U Matthew, director of manufacturing of Massey-Ferguson (United Kingdom), Ltd , and the first Lucas professor of engineering production in the University of Birmingham, died in Scotland, following a brief illness, on May 11, at the age of fifty-two

Thomas Urquhart Matthew was educated at George Heriot's School, Edinburgh, the Royal Technical College, Glasgow, and King's College, Cambridge He had production engineering and consultative experience in Great Britain and in South Africa, where he was technical adviser to the Government, before his appointment to the newly endowed Lucas chair in 1948 It was said, at the memorial service held on May 23, that the pioneer Department of Engineering Production which he developed at Birmingham would be his lasting memorial In 1955 Dr Matthew returned to industry as production director of Tube Investments, Ltd , and joined Massey-Ferguson a little more than a year ago

As Lucas professor, Dr Matthew was charged with determining and elucidating the principles of efficient production engineering, and the emergence of production engineering as a university discipline is, in large measure, a tribute to his ability He pioneered the application of scientific method to complex problems of production planning, organizing and control, and was one of the first to recognize the contribution that operational research could make in this field He was a modest, courteous and generous man, who devoted the whole of his time and energy, and considerable analytical gifts, to the service of industry and education for industry He served the Institution of Production Engineers in many capacities, and was a member of its Council, chairman of the Birmingham Section, and chairman of the Education Committee at the time of his death

In 1952, he led an I L O Technical Assistance Productivity Mission to the engineering and textile industries of India He was a founder-member of the International University Contact for Management Education, which brought him into close and continuing contact with his colleagues in Europe and America About the same time, he established, at Birmingham, the University Institute for Engineering Production to serve as a link between his postgraduate Department of Engineering Production and practising production engineers After his own return to industry, his keen interest and efforts on behalf of the Department remained undiminished

Dr Matthew leaves a widow and three sons

N A DUDLEY

Dr. H McCombie

DR HAMILTON MCCOMBIE, reader emeritus in chemistry in the University of Cambridge, died at Woking on May 31, aged eighty-two McCombie will be remembered for his distinguished service in the First World War, for his work in connexion with chemical defence, and by his many pupils in Birmingham and in Cambridge A Scot of the Scots, he was born in London, but in 1900 atoned by taking an ordinary M A of the University of Aberdeen A London B Sc with honours in chemistry followed, and he went on in the old tradition to Strasbourg to work under Thiele, getting his doctorate there in 1905

His first appointment was as lecturer in chemistry in the University of Birmingham, where he became interested in reactions in non-aqueous solvents, work which he continued later in Cambridge He was in Australia in 1914 to attend the meeting of the British Association There was the rush back home His enlistment in the Worcesters followed, but he was soon transferred to the Special Company, Royal Engineers, on its formation after the first German gas attack There his knowledge and steadfastness proved invaluable and were recognized by the awards of the M C and the D S O , the Croix de Guerre and two mentions in despatches

He was elected a Fellow of King's College, Cambridge, in 1919 and served his College and University until his retirement in 1945 In King's he became assistant tutor for natural sciences when C T Heycock retired, and he held this office until 1945, in the earlier years jointly with Sir Joseph Barcroft Kingsmen remember him with affection, and acknowledge the debt they owe to him He was wise in counsel, and long service on the College Council, on its Estates Committee and as an elector to fellowships was demanded from him and given ungrudgingly except, perhaps, when there was an important rugby match at Grange Road In the University he lectured on inorganic chemistry to the large class of second-year men about to take Part I of the Natural Science Tripos, and he ran a laboratory to which usually only scholars and exhibitioners were admitted Once in, a man could attend when he liked and do very much what he liked

Between the Wars, McCombie directed a very substantial volume of fruitful research, first on antidotes to mustard gas and, later, on the phosphorus gases During the Second World War he was a deputy chairman of the Joint Recruiting Board and acting head of the Chemical Laboratory after the death of Sir William Pope After his retirement he lived quietly at Woking to be near one of his daughters and his grandchildren

Prof P Hoffmann

PROF PAUL HOFFMANN, for many years professor of physiology in the University of Freiburg, died on March 9 in his seventy-eighth year He was a scientist of distinction and a man of great personal charm, modest, tolerant and wise His most important work dates from 1910, when he began the study of human reflexes by recording muscular activity with the string galvanometer His monograph, *Die Eigenreflexe*, published in 1922, remains a remarkable achievement, for it established for man many of the principles of reflex control of movement which have since been studied in greater detail in animals

In 1934 he succeeded von Kries as professor at Freiburg and became emeritus professor in 1954 His colleagues in many countries will sympathize with the University of Freiburg at the loss of an elder statesman, admired for his character as well as for his reputation as a scientist ADRIAN

NEWS and VIEWS

Editorship of *Science*

Dr. Graham P DuShane

DR GRAHAM P DUSHANE editor of *Science* (the official organ of the American Association for the Advancement of Science) since 1956, has resigned to become professor and chairman of the Department of Biology and dean of the Graduate Sciences at Vanderbilt University, Nashville, Tennessee Dr DuShane received his doctorate in zoology at Yale University in 1934 Following a research associateship at the University of Iowa and a National Research Council fellowship at Stanford University, he joined the faculty of the University of Chicago in 1936, where he taught for ten years before being appointed professor of biology in Stanford University in 1946 After six and a half years with the American Association for the Advancement of Science, he is returning to academic life in a newly created post that will give him responsibility for graduate education and research in the natural sciences, medicine and engineering at Vanderbilt University His appointment there will begin on September 1

Dr Philip H Abelson

As the new editor of *Science*, the Board of Directors of the American Association for the Advancement of Science has appointed Dr Philip H Abelson, member of the National Academy of Sciences and, since 1953, director of the Geophysical Laboratory of the Carnegie Institution, a position he will continue to hold while serving as editor of *Science* Prior to assuming the directorship of the Geophysical Laboratory, he was chairman of the Biophysics Section of the Carnegie Institution's Department of Terrestrial Magnetism During 1941–46 he was with the Naval Research Laboratory, engaged in the separation of uranium isotopes He received the doctorate in nuclear physics from the University of California in 1939

Convection Currents in the Earth

COMMENTING on the article by Prof J Tuzo Wilson, entitled "Cabot Fault, an Appalachian Equivalent of the San Andreas and Great Glen Faults and Some Implications for Continental Displacement" (p 135 of this issue), Prof J D Bernal, Birkbeck College, London, W C 1, writes "I find Prof Tuzo Wilson's account of convection currents in the Earth, in all but one respect, consistent and illuminating My objection is to the special and downward limited function he ascribes to the asthenosphere It seems to me to neglect the real evidence that exists for horizontal movements in the upper mantle

"If, as he implies in his Fig 2, the mid-ocean ridge cracks extend well into the mantle, why may not the return movements which occur under continental mountain chains do so as, indeed, is shown by the continuity of the epicentral surfaces of earthquakes above and below the asthenosphere? Furthermore, movement on these 40–50° shear surfaces may, as I have indicated elsewhere (*Nature*, 192, 123, 1961), be responsible for the building in of sial into the bases of the leading edge of continental sheets This might well take place by gravity differentiation of the intruded asthenosphere

"The puzzle of how the asthenosphere can appear on one hand as flowing and on the other as transmitting shear between mantle and crust may perhaps be solved by attributing to its substance a characteristic time of the order of some hundreds of years For stresses of shorter duration it would then, in common with the crust above and the mantle below, yield by shear faulting, for those of longer duration, by continuous plastic deformation"

Biochemistry at the Imperial College of Science and Technology

WITH the view of re-establishing biochemistry as a major discipline at the Imperial College of Science and Technology, Dr E B Chain has been appointed to the chair of biochemistry A gift of £350,000 was made by the Wolfson Foundation to provide the necessary laboratories, to be known as the Wolfson Laboratories It was intended that the new Wolfson Laboratories should be built behind the present Royal College of Science and that the rest of the space requirements of the Biochemistry Department should be met by adaptation of part of the existing building As a result of the University Grants Committee's subsequent approval in principle of the redevelopment of the site on which the Royal College of Science now stands, these plans were changed and a composite building for the whole of the Biochemistry Department has been planned, as the first stage of this re-development, near the west end of Imperial Institute Road The accommodation falls into the two distinct categories of laboratories and fermentation pilot plant The laboratories are designed and will be equipped for research in all important sectors of modern biochemistry, with special emphasis on the study of the reactions of intermediate metabolism and their regulation in higher animals and micro-organisms Laboratories will also be available for research in the disciplines bordering on this subject The fermentation pilot plant unit will consist of two separate elements a hall for vertical fermentation vessels and two chemical plant rooms, mainly for the extraction and purification of the desired substances and distillation of solvent A large underground solvent store is incorporated outside and adjacent to this building During the interim period until the building in South Kensington is ready, Prof Chain will continue his present activities as scientific director of the International Centre for Chemical Microbiology of the Istituto Superiore di Sanità, a position which he has held since 1949 when he left the University of Oxford Dr Ing R Falini, until recently in charge of the fermentation pilot plant at the Istituto Superiore di Sanità, will design the corresponding unit at the Imperial College

University of Saskatchewan Linear Electron Accelerator

THE Canadian National Research Council and the University of Saskatchewan Board of Governors have recently made available funds to the Department of Physics, University of Saskatchewan, for a linear electron accelerator and the erection of a building to house this machine and provide the ancillary research space Preliminary plans indicate that it will be a travelling wave machine composed of six separate accelerating sections each about 4 8 metres long operating in the $2\pi/3$, *TM* mode These will be powered by three *S*-band (2,856 Mc /s) klystron amplifiers of the type to be used on the 2-mile linear accelerator of Stanford University (Project *M*) Each klystron, delivering approximately 26 MW peak and 22 kW radio-frequency power average, has two output windows and will thus feed two of the accelerator sections An unloaded (zero beam current) energy of 250 MeV is anticipated, and, when loaded to deliver 20 kW of beam power, the energy should be in excess of 150 MeV Single shot operation is specified as well as repetition-rates up to 1,400 c /s

One feature of this machine will be the availability of exceedingly narrow pulses at the higher repetition-rates Widths of 10 mμsec are being specified in the design, although according to recent technological advances pulses as narrow as 1 mμsec are confidently expected The beam current in the narrow pulse is expected to exceed 2 amp Pulse widths may, however, be varied up to 1 μsec with correspondingly lower repetition-rates Since the *S*-band machine operates at 3×10^9 c /s and the electrons are bunched on the crest of each cycle with a phase spread of 20°, the electron beam is composed of individual electron bunches each 2×10^{-11} sec in duration with $\frac{1}{3}$ mμsec spacing between them A 1-mμsec pulse, as mentioned here, will thus be composed of 3–5 such bunches, each carrying 25 amp , that is, each bunch is $\frac{1}{2}$ cm diameter, $\frac{3}{4}$ cm long and contains 3×10^9 electrons The energy of the electron beam will be continuously variable from 5 MeV to the maximum value of 250 MeV Experiments in nuclear physics and radiation chemistry are being planned Intense beams of photons, electrons and neutrons will be available for these

Australian National Insect Collection

OVER the past thirty years the Division of Entomology of the (Australian) Commonwealth Scientific and Industrial Research Organization has been building up a collection of insects drawn from all States and Territories of the Commonwealth Intensive collecting by officers of the Division has been supplemented by numerous major donations and bequests, and to-day the collection is unquestionably the largest and most representative in existence of the insects of Australia and her dependent territories By proclamation in the *Commonwealth Gazette*, the collection has been named the Australian National Insect Collection in order to emphasize its status as a national heritage which it is the responsibility of the Commonwealth to preserve in perpetuity for scientific-study The title establishes an Australian equivalent of the Canadian and South African National Insect Collections and is to be welcomed for the assurance it implies regarding the future of the Collection The Collection will remain for the present in the custody of the Division of Entomology in Canberra, where it will play its part in the Division's research programme Co-operation with Australian and overseas museums will continue as in the past

The National Foundation for Scientific Research, Brussels

THE thirty-fourth annual report of the National Foundation for Scientific Research Brussels, for 1960–61 (Pp 384 Bruxelles Fonds National de la Recherche Scientifique, 1962), records the award of 104 research grants totalling 9 3 million francs to individual investigators, varying in amount from 25,000 to 200,000 francs Seventeen grants for special research work in the academic year 1961–62, totalling 11,308,088 francs, were also made and five extraordinary awards for 1960–61, amounting to 11,349,000 francs These include 2 25 million francs for the determination of coefficients of diffusion in alloys; 625,000 francs for an experimental study of the irreversible phenomena of relaxation of nuclear magnetism, 426,125 francs for a structural study of new amino-acids produced by different vegetables and fungi, including the isolation, determination of structure and synthesis of antibiotics, 750,000 francs for a study of high dispersion in the infra-red absorption spectra of vinyl and ethylene isotopes, 957,500 francs for the construction of an ultra-violet spectrograph of very high power, 994,845 francs for the purchase of apparatus for the study of electronic resonance in irradiation by X-rays in polymerization and in the radiolysis of organic liquids and alcohols in the solid state, 677,500 francs for the study of natural products, including indolic alkaloids, erythrophleums and *Morinda lucida*, 1,262,158 francs for the study of constructional materials in which deformation has an important influence in their behaviour in fatigue (including concrete, wood and plastics), and 588,900 francs for studies of the toxicology of pharmaceutical products, including the identification of metabolites and the standardization of pharmaceutical preparations based on enzymes A subsidy of 8 million francs was awarded to the Foundation for Scientific Medical Research for investigations on radioisotopes and cancer Other grants were made to assist attendance at scientific meetings in other countries Lists of awards are appended to the report, together with a list of publications by recipients of awards, 1958–61

Health in India

ON June 12, 1959, the Government of India set up a committee to review development in all matters relating to health and to formulate plans for the country in the third and subsequent Five-Year Plan periods The chairman was Dr A Lakshmanaswami Mudaliar, vice-chancellor of the University of Madras, who, with his distinguished colleagues, has now presented a report which should form a basis for improving health services in India for many years to come Even on such controversial issues as the limiting of population growth and the indigenous systems of medicine, the committee is clear and firm in its recommendations With all its implications for the future of India, the way in which the report has been prepared and presented merits praise, it could be read with profit by many health administrators outside India (Government of India Ministry of Health Report of the Health Survey and Planning Committee (August 1959–October 1961), Vol 1 Pp 482 + 56 Delhi Government of India—Ministry of Health, 1962)

Unesco and Termite Research

PROBLEMS of termite research were discussed at Unesco House in Paris during June 12–15 by a sub-committee recently set up on the recommendation of the International Advisory Committee for Humid Tropics Research Members of the sub-committee attending were Dr R L Araujo (Sao Paulo), Prof K Gosswald (Wurzburg), Prof P P Grassé (Paris), Mr W V Harris (London) and Dr M L Roonwal (Calcutta) Also present as observers were Dr E Ernst (Basle) for the International Union of Biological Sciences, and Dr L. G E Kalshoven (Blaricum) for the International Society of Soil Science The resolutions which had been adopted at the symposium on Termites in the Humid Tropics, arranged jointly by Unesco and the Zoological Survey of India at Delhi in October 1960, formed a basis for the discussions It was agreed that the international co-operation desirable in termite research, and in the dissemination of results of practical value in the control of termites as pests of buildings and crops, would best be achieved through Unesco Among the projects suggested for early consideration and action were (1) review of the influence of termite activity on soil fertility, (2) review of the methods used in combating termite damage to buildings and to tropical crops, (3) investigation of introduced termites, and of methods for restricting the spread of injurious species, (4) co-ordination of methods for the laboratory testing of termite resistance in materials, (5) standardization of measurements used in termite taxonomy, and of terminologies used in termite biology

Refuse Disposal

EVERY year local authorities in Great Britain dispose of nearly 100,000,000 cubic yards of refuse, weighing about 13,000,000 tons Up to 20 per cent by weight of this is worth salvaging, and, as living standards rise, the proportion increases Many local authorities have central refuse sorting plants where these materials are extracted and sold back to industry Stoke-on-Trent, for example, has an income from this source of 20*s* for every ton of refuse handled Local authorities are apt to be cautious in their approach to any positive change in their established practice of refuse disposal, but, if they had a statutory duty to protect the landscape, carrying equal weight with their public health obligations, it is likely that the advantages offered by new methods of refuse and sewage disposal would compel their speedy adoption The Sheffield and Peak District Branch of the Council for the Preservation of Rural England has published a useful pamphlet by J C Wylie on this subject which is specially valuable for the information it gives on composting in practice (price 2*s*) The main advantages of composting are that no large area of land is required, composting plants can be permanently placed in close proximity to the areas from which the refuse is collected, the composting process, when aerobically carried out, is hygienic and is not a nuisance It offers a solution to the difficult problem of sewage sludge disposal, no more manpower is called for than is required under present systems of disposal, the prospects for selling compost are excellent

Norsk Polarinstitutt, Årbok, for 1960

THE Norsk Polarinstitutt has recently published the first of a new series, its *Årbok* (Yearbook) for 1960 This addition to the existing *Skrifter* (papers) and *Meddelelser* (communications) which have been published by the Institute for some years will fulfil several functions It will contain the annual report of the Director, general information about the Norsk Polarinstitutt, information on scientific work carried out by foreign expeditions in Norwegian Arctic and Antarctic territories, and shorter scientific papers of general interest. In the 1960 *Årbok*, about 80 per cent of the text is in English, so its use will not be restricted to those with a knowledge of Norwegian Shorter papers cover items such as the discovery of footprints of the dinosaur in the lower cretaceous of Vestspitzbergen, a discussion of the fossil *Gigantaspis* which has only been reported once before, and a general paper surveying height limits for vascular plants in Svalbard (in Norwegian) A short report of a glaciological survey of Maudheim in 1960, eight years after the station of the Norwegian-British-Swedish Antarctic Expedition was abandoned, throws useful light on processes of bottom melting and surface accumulation on ice shelves A review in English on recently published Russian work on the bathymetry of the region between Spitsbergen and Greenland shows that the postulated Nansen Ridge connecting the two lands does not exist, and a trough of more than 3,000 m in depth separates the two regions Another useful survey is that on absolute age determinations on rocks from Dronning Maud Land, Antarctica, by recent Belgian, Japanese and Russian expeditions Several other articles, the annual report and a short history of the Institute complete the *Årbok*

Scientific Research in British Universities and Colleges, 1961–62

Scientific Research in British Universities has now been superseded by the Department of Scientific and Industrial Research's publication entitled *Scientific Research in British Universities and Colleges* (1961–62 Pp xvii+622 London H M S O, 1962 32*s* 6*d* net) The hand-book lists research being carried out at present in universities and colleges and advanced technical colleges and regional technical colleges in England and Wales and equivalent colleges in Scotland and Northern Ireland It describes the nature of the project in sufficient detail to indicate the sort of research done by the various scientific departments and individual teams of investigators, but does not refer to the social science and industrial administration except where work in this field normally occurs within the science faculty or technical department The format of the hand-book remains the same and the name- and subject-indexes are separate Copies of the hand-book are available from the Department of Scientific and Industrial Research, State House, High Holborn, London, W C 1

Publications of the Instituto Antartico Argentino

DURING recent years the Argentine Antarctic Institute has played an active part in developing scientific investigations of Antarctica In addition to being responsible for the operation of the Ellsworth-General Belgrano group of stations at the head of the Weddell Sea, the Institute has developed a good library, has a scientific staff working on Antarctic results for publication, and is the main centre of Antarctic research in the Argentine The symposium on "The Antarctic" held there in 1959 was attended by 57 representatives of other countries, and was most successful as a means of exchanging early information on the results of research of the International Geophysical Year The Institute publishes several series which include the *Boletin del Instituto Antartico*

Argentino which appears twice per annum and contains short articles of general interest on Antarctic and Institute activities *Contribuciones del Instituto Antartico Argentina* present scientific papers on original work and some review papers, such as No 49, "Progress Recientes en Glaciologia Antartica", by R N Panzarini Some 53 *Contribuciones* have appeared so far *Publicaciones del Instituto Antartico Argentino,* of which eight have now appeared, are monographs of greater length and wider scope than many of the *Contribuciones,* "Estudio Geologicao-Petrografico de Caleta Potter, 25 de Mayo, Islas Shetland del Sur" by N H Fourcade being the most recent one The Institute also publishes a translation in Spanish of the *SCAR Bulletin,* which records the activities of the Scientific Committee on Antarctic Research of the International Council of Scientific Unions The Instituto Antartico Argentino has thus become the most important source of Spanish language publications dealing with Antarctic scientific research, and it is playing a valuable part in the twelve-nation co-operative research programme in Antarctica

Library Reference Services in the United States

Scientific Information Notes for April–May 1962, issued by the National Science Foundation, reports the selection of twelve universities and libraries in the United States to make more widely available the unclassified results of Federally sponsored research and development The Department of Defence, National Aeronautics and Space Administration and the Atomic Energy Commission, which it is estimated produce 90 per cent of the Government s unclassified technical reports, have agreed to provide copies of their reports for deposit in these centres, which will organize and maintain a cumulative library collection of all such material, providing personal reference service for the general public inter-library loans, and, where appropriate, assistance in obtaining copies for retention The National Federation of Science Abstracting and Indexing Services is developing, with the support of the National Science Foundation, a programme defining the present and future role of United States scientific abstracting, indexing and reviewing services The Biological Sciences Communication Project of the American Institute of Biological Sciences has inaugurated a programme for training graduate-level students to become "Science Information Specialists" The same Institute is conducting a literature survey to determine the proportion of biological research supported by the Federal Government

Assessing Reference Library Efficiency

In an article in the *Journal of Documentation* for June, P F Cole takes a new look at 'reference scattering' He claims that the slope of the curve obtained by plotting the cumulative fraction of total references against the logarithm of the cumulative fraction of total titles gives a 'reference-scattering coefficient' which may be characteristic of the subject field The reference-count method is regarded as giving untrustworthy results, but this reference-scattering coefficient can be used to derive a general relation between number of references and number of titles and provides a yardstick for assessing the efficiency of correlation between the holdings of a petroleum industry library, for example, and the needs of its users It can also be used as a criterion for detecting abnormalities in the results of literature usage surveys In the same issue, Dr A N Oppenheim contributes an interesting survey of the reading habits of students at the London School of Economics where Dr Oppenheim is a lecturer in the Department of Social and Industrial Psychology.

Magnesium Oxide and Hydrochloric Acid from Concentrated Sea Bittern

The mother liquor that remains after sodium chloride has been crystallized out of sea-water is termed bittern The production of magnesium oxide and hydrochloric acid by the thermal decomposition of crude magnesium chloride, recovered from sea bittern, has been attempted under different conditions In a procedure recently outlined by R K. Sapre and M P Bhatt, of the Central Salt Research Institute, Bhavnagar, debrominated bittern is concentrated first by solar evaporation and then, by forced evaporation, into a liquor which, on cooling, sets into a cake containing 46–50 per cent magnesium chloride (*J Sci Indust Res* , 21D, No 2, February 1962) The cake is then decomposed in a furnace by direct firing with an oil burner at 500°–700° C and the gaseous products cooled and condensed to give hydrochloric acid of 25 per cent concentration The residue containing 82 per cent magnesium oxide, on washing and dehydration at 500°–600° C , yields magnesium oxide of 96 per cent purity The recovery of hydrochloric acid is 76–78 per cent

Epidemiology of Skin Diseases in Africa

Dr James Marshall, head of the Department of Dermatology, University of Stellenbosch, writes that a pilot survey on the epidemiology of skin diseases in Africa has yielded such interesting material that he is preparing, with the assistance of the South African Council for Scientific and Industrial Research, to make a large-scale investigation of the distribution and incidence of skin diseases on the continent of Africa The ultimate aim is to establish a central office for information and a reference library of literature and photographs Dr Marshall wishes to approach not only those in scientific and academic institutions, but also anyone who practises or has practised in Africa who could supply information, even if it were only on a limited field of the question Questionnaires can be obtained from Dr James Marshall, Simon's View, Sorrento Road, St James, C P , South Africa

Meteorology and Poliomyelitis

Bio-meteorology is a branch of atmospheric science which has not received a great deal of attention in Britain In particular, the relationship between health and the weather is a subject of wide interest, a better understanding of which could be of considerable practical benefit to many Some of the relatively few investigations which have been made on such relationships in the United Kingdom are summarized in a note on the "Importance of Meteorological Factors to the Incidence of Poliomyelitis" by E N Lawrence (*Brit J Prev Soc Med* , 16, 46, 1962) The main parameters which have been investigated are dry-bulb temperature, vapour pressure and relative humidity Of these, it appears that the incidence of polio is highly correlated with temperature There are also indications of a positive correlation with humidity, though Spicer, a co-worker in these investigations, found a negative correlation with relative humidity and suggested that atmospheric drying power may be the important factor with which to correlate the incidence of the disease

Other workers, such as Hemmes, Winkler and Kool (*Nature*, 188, 430; 1960), conclude that relative humidity indoors is an important environmental factor contributing to the seasonal fluctuations of the morbidity of the disease, and show that the death-rate of the virus is diminished at higher relative humidities. Since the normal range of indoor temperature is restricted, indoor relative humidity may well be governed by the outdoor vapour pressure. Thus, high outdoor vapour pressure could be associated with high indoor relative humidity and both these parameters could be positively correlated with poliomyelitis incidence.

Anopheles hyrcanus and Malaria in East China

Anopheles hyrcanus sinensis, the chief component element of the anopheline fauna in South-east Asia, is not a single taxonomic unit but a species of the *Anopheles hyrcanus* group. This group includes a number of closely allied species which show only slight differences in adult morphology but diverge widely in behaviour, physiology and in their relation to malaria transmission. Both malaria and filariasis are prevalent in various areas in the lower Yangtze Valley, where the vector is said to be '*Anopheles hyrcanus sinensis*'. In the hilly tracts of Anhwei, Chekiang and Kiangsu provinces, malaria and filariasis are both prevalent. Investigations show that the major anophelines are two sibling species of the *Anopheles hyrcanus* group, one laying wide-decked eggs and the other narrow-decked eggs. The former is much more numerous than the latter and is more widely distributed. In their investigations for distinguishing characters of the two sibling species in the adult stage, Ho Ch'i *et al.*, of the Laboratory of Malariology, Institute of Parasitic Disease, Chinese Academy of Medical Sciences, Shanghai, found that the presence or absence of *T*-shaped cloudy markings on the membranous pleuron of the female abdomen is a reliable method of identification (*Chinese Medical Journal*, 81, No. 2; February 1962). Studies on the bionomics of the two anophelines—their food habits, resting habits, breeding habits, nocturnal activities, seasonal distributions, and hibernating characteristics—showed that differences in food habits, breeding habitats and hibernations are of epidemiologic importance. In the hilly tracts of the lower Yangtze Valley, where both malaria and filariasis occur and both anophelines are present, *A. lesteri* is the more important vector; *A. sinensis*, though also a vector, is of minor importance. In large open plains, where malaria and filariasis are endemic in a low degree, and only *A. sinensis* is found, it is responsible for the continuous occurrence of malaria, its seasonal variations, and at times outbreaks of malaria epidemics.

Flint Burins from California

WHEN making a flint implement from a blade or flake the object is held horizontally, and vertical blows are given to produce a trimmed edge. In the case of a burin, however, the blade is itself held vertically and a blow given, resulting in a flake scar which runs down the edge of the blade. When two such flake scars on the opposite sides of the blade intersect the result is a *bec de flute* or ordinary burin, a sort of flint screwdriver in appearance; when the burin facet is backed against a trimmed edge the tool is called an angle burin. Burins were for a long time considered to belong exclusively to the Upper Palæolithic and Mesolithic cultures of western Europe. From time to time an odd example occurred elsewhere from Australia to America, but these were usually considered to be chance manufactures. A whole collection of these tools, associated with small blades and cores, which in Europe would be classed as Mesolithic but which are said to come from Santa Cruz Island off California, have now been described. They were collected by Léon de Cessac as long ago as 1878 and have since been in the Musée de l'Homme at Paris. Cessac made many excavations in the Santa Barbara region on the mainland, as well as on several of the offshore islands. For the first time the collection has been studied by R. F. Heizer, and the results published with the collaboration of Harper Kelley in the *Proceedings of the American Philosophical Society* for 1962. The collection, as judged from the illustrations, is certainly extraordinary as coming from California. Accepting that there has been no admixture since 1878 when they were given to the Musée de l'Homme, it is not too easy to believe that an assemblage of tools so typical of Western European cultures could have occurred all together in sites off the west coast of America.

The Red Ochre Culture of the Upper Great Lakes of North America

THE March issue of *Fieldiana: Anthropology* contains an article on "The Red Ocher Culture of the Upper Great Lakes and Adjacent Areas" by R. E. Ritzenthaler, the curator of the Milwaukee Museum and G. I. Quimby, the curator of the Museum at Chicago (Vol. 36, No. 11. Pp. 243–275. Chicago: Chicago Natural History Museum, 1962. 1 dollar). The name "Red Ocher Culture" was first used in 1937 and refers to finds made in Wisconsin, Iowa, Illinois, Indiana, Ohio, Michigan and Ontario. It thus has a wide distribution. Common features at all sites are the use of a layer of red ochre to cover the graves, the burying of the corpses in a flexed position in pits and in sand, the occurrence of large ceremonial flint blades (sometimes up to 19 in. in length) and other stone tools, and of some copper awls, celts, knives and points.

Tenth Pugwash Conference

MORE than two hundred scientists from all over the world will meet in London during September 3–7 to consider how science can help to solve some of the world's problems. The Conference will be the tenth organized by the Pugwash organization of scientists, and the first to be held in London (Pugwash is the name of the village in Nova Scotia where the first conference was held in 1957). Among the participants will be sixty scientists from the United States. The British delegation will comprise thirty, and a similar number will come from the U.S.S.R. At least thirty other countries will be represented. The Royal Society will act as host for the London Conference, which will be held in the Russell Hotel and will be in private. An account of the proceedings will, however, be made public by participants at the Conference at the end of each day.

Among the subjects to be discussed at the Conference are the position of the scientist in the community, the problem of world security, international collaboration in science and the part which science can play in the developing nations. There will also be discussions of the ways in which science can assist in education. The Conference will also receive a report on measures for arms control prepared by a conference to be held at Cambridge in the week of August 27.

Operational Research for Management

The University of Hull is offering as from October a one-year postgraduate diploma course in operational research for management Operational research is one of the several management tools designed to provide industry with the means of reaching informed decisions It is an important basis of modern scientific management In no sense does it attempt to replace management Although related to them, it is to be distinguished from such other management aids as work study, ergonomics and organization and methods The techniques of operational research are mainly mathematical and statistical in character, many of them were used primarily for military purposes, but to-day they are used increasingly in modern industry Applicants for the course should have some prior knowledge of mathematics, but it will otherwise be open to graduates in any subject and, in special circumstances, to non-graduates also In addition to graduates in economics and statistics, a training in operational research can add considerably to the qualifications of physicists, chemists and engineers intending to go into industry, and much of the course will be concerned with the application of scientific techniques to practical management and industrial problems Further information can be obtained from the Registrar

The Paul Instrument Fund Awards

The Paul Instrument Fund Committee has made grants as follows £2,736 to Dr S Evans, senior assistant in polar research, University of Cambridge, for the development of an instrument for measuring the depth of continental ice sheets by a radar technique, £10,500 over a period of two years to Dr W R S Garton, reader in physics, University of London, and Dr R C M Learner, research associate, Imperial College of Science and Technology, for the construction of a high-resolution broad-range vacuum spectrograph, £3,600 to Prof J W S Pringle, Linacre professor of zoology, University of Oxford, for the construction of apparatus for making various physical measurements on muscle by sinusoidal dynamic analysis The Paul Instrument Fund Committee, composed of representatives of the Royal Society, the Institute of Physics and the Physical Society and the Institution of Electrical Engineers, was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much-improved types of physical instruments and apparatus for investigations in pure or applied physical science"

The Leopoldina German Academy of Sciences Elections

The Deutsche Akademie der Naturforscher Leopoldina, Halle, recently elected the following new members in the sections indicated *Mathematics*, Prof L Collatz (Hamburg), Prof L Rédei (Szeged), Prof R Sauer (Munchen) *Physiology*, Prof G von Békésy (Cambridge, Mass) *Physiological Chemistry*, Prof F B Straub (Budapest) *Pharmacology*, Prof J H Burn (Oxford), Prof U S von Euler (Stockholm), Prof J H Gaddum (Cambridge), Prof O Krayer (Boston, Mass), Prof L Lendle (Gottingen), Prof K Repke (Berlin-Buch), Prof B K M Uvnas (Stockholm), Prof W Wilbrandt (Berne) *Hygiene*, Prof P Grabar (Paris), Prof E G Nauck (Hamburg) *Internal Medicine*, Prof M Gulzow (Rostock), Prof N Henning (Erlangen)

Announcements

Dr C Bloomfield has been appointed by the Lawes Agricultural Trust Committee to succeed the late Dr A Muir as head of the Pedology Department of Rothamsted Experimental Station, Harpenden, Herts

At the annual general meeting, held on June 20, Dr J O Irwin was elected president of the Royal Statistical Society for the ensuing year Prof P Armitage, Mr B P Emmett and Miss S V Cunliffe were elected honorary secretaries, and Mr C T Saunders was elected honorary treasurer Prof P Armitage was awarded the Society's Guy Medal in Bronze

The Council of the Plastics Institute has accepted an offer from Temple Press, Ltd , to mark the Centenary of Plastics year This award, to be known as the 'Plastics' Centenary Award, will comprise a cash award of £75 to be given every two years, to the candidate who achieves the best overall results in the Plastics Institute Examination A detailed specification for the award can be obtained from the Plastics Institute, 6 Mandeville Place, London, W 1

The North Atlantic Treaty Organization is offering financial support for short courses, of two weeks or more duration, at which scientific topics are discussed at an advanced level The grant may be used for administrative expenses, publication of proceedings, or to subsidize the expenses of foreign visitors Further information can be obtained from the Scientific Affairs Division, North Atlantic Treaty Organization, Place du Maréchal de Lattre de Tassigny, Paris 16^{e}

The fifth international congress on "Electron Microscopy", organized by the Electron Microscope Society of America, will be held in Philadelphia during August 29–September 5 Further information can be obtained from the Fifth International Congress for Electron Microscopy, 7701 Burholme Avenue, Philadelphia 11, Pa

The ninth international symposium on "Combustion", arranged by the Department of Thermal Engineering at Cornell University under the auspices of the Combustion Institute will be held at Cornell University during August 27–September 1 Further information can be obtained from the Combustion Symposium Office, Upson Hall, Sibley School of Mechanical Engineering, Cornell University, Ithaca, New York

The third international meeting of the Collegium Internationale Neuro-Psychopharmacologicum will be held in Munich during September 2–5 The programme will include the following symposia methods of comparison of behaviour changes with drugs in animals and man, effectiveness of drugs in relationship to psychological and social forms of treatment, ten years of psychopharmacology, critical assessment of the present and future Further information can be obtained from Prof W de Boor, Kerpenerstrasse 4, Cologne, or Prof F A Freyham, Saint Elizabeth's Hospital, Washington, D C , or Dr P D Bradley, the Medical School Birmingham

Erratum In the biographical note concerning Mr A Stratton that appeared on p 918 of the June 9 issue of *Nature*, the penultimate sentence should read "In 1951 he obtained an M Sc (London) degree in mathematics and in 1957 a B Sc (Exeter), *ad eundem*"

RECRUITMENT OF BRITISH PERSONNEL FOR SERVICE OVERSEAS

IN reply to a question in the House of Commons on May 22, the Secretary for Technical Co-operation, Mr Denis Vosper, said that grants of £11,000 in 1959–60, £2,000 in 1960–61 and £17,500 in 1961–62 had been made to Voluntary Service Overseas, the grant for 1962–63 was under consideration He fully agreed as to the value of the work and hoped that he might have something to add after his talks with the voluntary bodies concerned on May 23 It was part of his task to meet the requests of overseas countries for technical people, and this could not be met on a voluntary basis

On May 29, Mr Vosper said that as a result of discussions with representatives of many voluntary societies and other interested people, a scheme had been worked out to co-ordinate and stimulate the recruitment of volunteers for overseas service These steps are supplementary to the general recruitment activities of his Department described in a White Paper also issued on May 29 He thought comparison of Voluntary Service Overseas with the American Peace Corps was accordingly misleading The present programme of Voluntary Service Overseas would send 160 individuals overseas, but others were sent by other organizations He hoped for a considerable advance on this number and welcomed the suggestion that voluntary service should be put on a wider basis One proposal of the statement circulated by Mr Vosper was for a co-ordinating committee on which would be represented all the bodies concerned and which would co-ordinate existing and stimulate further activities

The statement refers to the great and growing interest in the service overseas by volunteers and to the meetings held by the Department with voluntary societies and other bodies concerned At these meetings it was agreed that recruitment dispatch overseas of volunteers would best be discharged by the voluntary bodies, but that their work could be made more effective by co-ordination A committee, known as the Voluntary Societies Committee for Service Overseas, had been established to co-ordinate generally the work of voluntary societies in the whole field of voluntary service overseas by school-leavers, young graduates and other qualified or trained personnel and to work out a scheme for graduates It would formulate general policy for recruiting graduate volunteers, maintain contact with universities, colleges, industry and commerce to encourage applications for voluntary service, and disseminate information about the progress of the scheme The voluntary societies would remain responsible for all executive action connected with recruitment dispatch and administration of volunteers, including graduates, as well as the selection of graduates Dr J F Lockwood would be chairman of the Committee, which would include representatives of the National Council of Social Service, the British Council of Churches, the Overseas Development Institute, Voluntary Service Overseas, the Department of Technical Co-operation, the British Council, the National Union of Students, and six members from universities, colleges of advanced technology, schools, industry and commerce

The National Council of Social Service has agreed to provide a secretariat and the Committee would start at once to plan a campaign for recruitment of graduates as volunteers for the summer of 1963, while for 1962 it was planned to send fifty graduates to Africa on a pilot scheme for volunteer teachers The British Government would pay for return passages and terminal grants and meet some other incidental expenses In addition, the United Nations Association, the National Union of Students and International Voluntary Service were planning to send abroad this year a few graduate volunteers for a year or more, and Voluntary Service Overseas continue to build up their existing substantial programmes for sending school-leavers overseas If suitable schemes were presented by these bodies, the Department of Technical Co-operation would be ready to provide financial support up to an amount similar to that for the pilot scheme for volunteer teachers

The White Paper *Recruitment for Service Overseas Future Policy** sets forth the present nature of recruitment through the British Government for service in both independent and dependent countries overseas and for international organizations It examines the probable development of demand for such staff in the next four years and the problems likely to arise, and describes the steps being taken by the Department of Technical Co-operation to meet the demand Apart from taking account of the recommendation of the Select Committee on Estimates for the establishment of a Commonwealth Advisory and Technical Service, the White Paper is of interest as recognizing the existence of the Overseas Research Council Besides providing a concise statement of the policy the Department proposes to pursue, it includes a detailed summary of action being taken in specific fields and some statistics of appointments

The White Paper draws the conclusion that the proposal of the Select Committee on Estimates does not take sufficient account of the nature of the demand or the character of the supply The Department therefore proposes to apply the basic principle that most recruitment in future for service overseas within the sphere of the Department should be for limited periods which form part of a career based primarily in Britain or in the service of a British institution The way in which this principle is applied will vary widely from one profession to another, but the major thread is that people should find it easy, and preferably advantageous, to resume their professional employment in Britain (or with a British Institution) after a period of service overseas

The formal terms of appointment will be either contract, loan or secondment A new and more flexible form of contract, adapted to present overseas conditions, is now being prepared The National Council for the Supply of Teachers Overseas has asked all United Kingdom educational institutions to allow teachers going to suitable appointments overseas to preserve the continuation of their pensions and to have the right of return to their previous employment (though not necessarily their previous post). In the university field the flow of teachers on long-term conditions of service overseas requires supplementing by arrangements for supplying staff for short-term appointments tailored to meet the specific needs of overseas universities. A small committee has been set up by the Department to make possible and stimulate such arrangements through the British universities. Arrangements for the loan of staff already exist in the Civil Service and nationalized industries. It will be the aim of the Department of Technical Co-operation to develop and maintain existing arrangements of this kind and to introduce them in appropriate fields where they do not exist, in general, to encourage large employers in the public and private sector to accept the need to release qualified staff as required for service overseas.

---

* Department of Technical Co operation *Recruitment for Service Overseas—Future Policy* Pp 29 (Cmnd 1740) (London H M S O , 1962) 2*s* net

For arrangements of this kind to be effective, it is important that the employers concerned should take an active interest in the encouragement of such service overseas, and that the value of such a service should be recognized by employers in Britain and taken into account in considering employees for promotion. It is a major task of the Department of Technical Co-operation in conjunction with other Government departments and the relevant professional bodies to achieve this.

The White Paper recognizes that the lending of staff in this way may be troublesome and inconvenient, but none the less, from the point of view of Britain, it is important that all in a position to do so should co-operate in making such service possible. Further, the Government must give the lead and all Government departments will make a special new effort to release staff for overseas service when they can, and staff will be encouraged to volunteer for this purpose. It is also proposed to examine the position profession by profession, and to discuss the matter with the Federation of British Industries and with certain large-scale employers. In the field of scientific research it has been possible to appoint people to home-based establishments on terms which require their release for overseas assignments from time to time, so that when the scientist concerned is not undertaking research overseas, he can be suitably employed on research in Britain. It is recognized, however that the number of people employed in this way is unlikely ever to be high.

CHEMICAL APPLICATIONS OF ELECTRON SPIN RESONANCE

A SHORT course dealing with "Chemical Applications of Electron Spin Resonance" was held at the Department of Chemical Technology, Bradford Institute of Technology, on February 15–16, 1962. It followed an analogous symposium last year on 'Applications of Nuclear Magnetic Resonance Spectroscopy" and was attended by about fifty chemists and physicists from the chemical and electronics industries and the universities and technical colleges.

Opening the meeting, Dr. E. G. Edwards, principal of Bradford Institute of Technology, noted the interaction between science and technology, appropriate to a College of Advanced Technology, which was implicit in the application to chemistry of a technique based on microwave equipment and large magnets of variable field.

In his introductory survey of electron spin resonance, Prof. D. J. E. Ingram (University of Keele) showed that the enhanced magnetic energy separation in a given field arising from the larger magnetic moments possessed by electrons than nuclei led both to a higher absorption frequency (microwave rather than radio) and also to a higher net absorption and sensitivity. Indeed, as few as $10^{11}\Delta H/\tau^{1/2}$ unpaired spins, where ΔH is the line width in gauss and τ is the time-constant in seconds, could be detected from the integrated line intensity. Discussing the hyperfine interaction between the unpaired electron and nearby nuclear spins, on which much of the chemical utility of electron spin resonance depends, Prof. Ingram outlined the two contributions to the Hamiltonian: the dipolar effect, angular dependent unless averaged out, and the isotropic Fermi contact term.

Dr. B. A. Coles (University of Oxford) contrasted the experimental techniques of shorter wave-length spectroscopy with those appropriate to operation in X (around 9,400 Mc./s.) and Q (around 35,000 Mc./s.) bands, and illustrated the mode patterns in wave guides and cavities. Replacement of the simple transmission cavity by a reflexion cavity and a microwave 'crossroads' bridge or preferably one of the 'roundabout' or ring type increases the useful proportion of microwave power measured. Further, the high sensitivity associated with a low band-width/frequency ratio is achieved by (1) adopting phase-sensitive detection (with small modulation amplitudes, the first differential of the absorption is recorded), and (2) modulating the field at 100 kc./s. rather than 50 c./s. However, if the resulting modulation satellites at about 35 mG limit resolution, it is preferable to superheterodyne sources of, say, 10,000 and 10,030 Mc./s. and to use low-frequency modulation.

A manufacturers' session followed, in which Mr. I. G. Morgan (Hilger and Watts, Ltd., and Microwave Instruments, Ltd.) described the 100 kc./s. Microspin spectrometer for Q and X band operation, Mr. J. M. Babb (Varian A.G.) emphasized the research and service activities in electron spin resonance of his organization, and Mr. J. L. Williams (Associated Electrical Industries, Ltd.) and Mr. M. J. Amos (Mullard, Ltd.) referred to magnet systems suitable for electron spin resonance.

The next three speakers discussed the application of electron spin resonance to free radicals. Dr. P. B. Ayscough (University of Leeds) showed how the nuclear hyperfine structure of narrow lines from free radicals in dilute solution could reveal the detailed unpaired electron distribution. According to the complexity of the spectrum and the condition of the specimen, a concentration of 10^{-4}–10^{-6} M was needed for identification rather than mere detection, for varying concentrations, the minimum was about ten times higher. Since these are larger than the stationary concentrations met in alkyl systems, aromatic and other comparatively stable radicals had been most studied. Dr. Ayscough then dealt with the problems of distinguishing between equivalent and non-equivalent protons and of synthesizing spectra for various values of hyperfine splitting constants In some radicals, for example, triphenylmethyl, which can be used as a reference, the total of spin densities computed was greater than unity because densities at some carbon atoms have spin opposite to that of the unpaired electron (although the signs are not determined by the electron spin resonance data)

On irradiation at low temperatures, solid polymers frequently yield measurable free radical concentrations which decay slowly at room temperature Mr M G Ormerod (Royal Military College of Science, Shrivenham) described the use of electron spin resonance as a check of purity, for detection of intermediates, and for the estimation of degree of cross-linking, future work might include the effects of water and of radiation protection additives Measurements with drawn fibres sometimes enabled the nature of the radical(s) to be identified, but resolution was lower than with irradiated single crystals, which formed the subject of the talk by Dr A Horsfield (Varian A G , Zurich) In dilute free-radical systems trapped among the host molecules of the crystal matrix, not only can the irradiation damage, such as stripping of a hydrogen atom, be investigated, as with polymers, but also the anisotropic hyperfine splitting associated with specific chemical groups may be obtained Among the simple negative inorganic radicals studied recently by D H. Whiffen and collaborators, Dr Horsfield mentioned the $SO_3^{\cdot -}$ ion obtained from salts containing the $—SO_3^-$ group, the single line spectrum is split into a quadruplet by the sulphur-33 nucleus ($I = 3/2$) in its 0 7 per cent natural abundance In $\dot{C}H(SO_3)_2^{2-}$, hyperfine splitting due to protons on nearby $CH_2(SO_3)_2^{2-}$ host ions has also been detected in crystals of the potassium salt

Dr A Carrington (University of Cambridge) turned from free radicals to the other main field of application of electron spin resonance to chemistry, transition metal ions The effect of the exact ligand symmetry on g-values and the fine structure resulting from several unpaired electrons were considered for dilute crystals of complexes Hyperfine interaction with ligand nuclei possessing magnetic moments as with the nitrogens in hæmoglobin, could provide crystallographic information Finally, Dr Carrington pointed out that, whereas the meeting had been devoted so far to the study of ground states, electron spin resonance could provide a means of studying excited states Recently, Hutchison had detected resonance in the phosphorescent state obtained from ultra-violet irradiation of a dilute solid solution of naphthalene in durene D W JONES

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES ANNUAL CONGRESS

AT the invitation of the Horsham Urban District Council and the Horsham Natural History Society, the South-Eastern Union of Scientific Societies held its sixty-seventh annual congress at Horsham during May 25–27 under the presidency of Dr Maurice Burton The headquarters of the congress was at Collyer's School, by kind permission of the headmaster

The delegates were welcomed by the chairman of the Urban District Council, Councillor Cullen, and J Southwood, the president of the Natural History Society They emphasized the need of collecting information regarding the footpaths in and around Horsham, continual development had caused the loss of many paths and often there was considerable difference between the amenities of an ancient pathway and the alternative diversion

The young naturalists' evening consisted of a 'brains trust', questions being debated by a panel under the chairmanship of Maxwell Knight The panel particularly stressed the desirability of biological control where damage was caused by animals, pointing out that spraying with insecticides over long periods cannot be justified There was an increase in the mortality-rate of birds last year, one cause being that insufficient notice was taken of the manufacturers' instructions, another was the careless throwing aside of used containers with contaminated water

The presidential address was given by Dr Maurice Burton, whose subject was "The Fallibility of Human Observation" Wishing to know the difference between biology and natural history, he had consulted *The Oxford Dictionary*, which defined natural history as "the unintelligent study of biology" Although startled at first, he had to agree that this was correct, although the choice of wording was unfortunate Seeing is a purely physical process, to be likened to the operation in a camera, while observing is this plus other mental processes It has often been said that it is "far more virtuous to observe than to see", but this is not always correct Dr Burton spoke of his experience when surprised by the appearance of a white bird in his holly tree On using his binoculars he discovered he had been looking at the underside of the holly leaves, members of his family at the same time experienced the same illusion He followed with the example of a class shown a drawing of an isosceles triangle with a rectangle attached to the centre of the base Halves of the class were shown the diagram independently, one having it described as a trowel, the other as a Christmas tree Later, when asked to draw what they had seen, they showed all graduations from a trowel with a long handle to a Christmas tree On another occasion he asked a friend, well informed on the subject-matter, to help by proof reading The galley and paginated proofs were passed, but, on receiving his author's copy, he was dismayed to find a caption under an illustration spelt incorrectly With the book open at this page on his desk, he was visited by the proof reader who, glancing from a distance of 3 ft , exclaimed "Did I pass that ?" His observation during proof reading made him see what he had expected, not what was

The important thing in studying animal behaviour is to look, look and look, to allow the impression to soak in, not permitting a previous impression to be formed Dr Burton considered that verbal pictures ran the risk of being wrong, drawings were better He showed and commented on a number of slides dealing with the 'Loch Ness monster', his examination had convinced him that the creature drawn and photographed was an otter, the other pictures were of a motor-boat. He concluded by saying that his analysis of this problem showed that maybe the dictionary was right and a naturalist could be an unintelligent biologist

The presidential address to the Zoological Section was given by R M Long, on "Butterflies and Moths of the Horsham Area" The address was illustrated by colour slides from the president's photographs, dealing mainly with the camouflage of many of the species in the area He spoke of the success achieved with his mercury-vapour-lamp trap as many as a thousand specimens were taken on a good night He had recorded 31 species of butterfly and 347 of moth in his garden near the Carfax at the town centre He asked that, when particular trees and hedgerows were the habitat of the rarer species, the Council for Nature and the County Naturalist Trust be notified to enable an order to be obtained for their preservation

The Archæological Section was addressed by the president, G P Burstow, on "Recent Excavations in Sussex" He spoke of the excavations with which he had been associated, especially at Monkdown Court, near Findon, where three years work had revealed 900 post holes of an iron-age village occupied between 500 and 300 B C There was evidence of drying racks, storage pits and a quantity of pottery with hæmatite surface The site was later occupied by the Romano-British, a shrine connected with the worship of the ox had been uncovered, a possible association with a local Celtic god Vast quantities of Roman pottery had been recovered, and many bronze objects, notably a plaque of a charging boar Mr Burstow described other excavations at Ranscomb Hill near Mount Caburn and Balcombe quarry It was in middle Sussex where research work was most needed, a mistaken idea that it was unoccupied in ancient times being due to insufficient archæologists having been interested in the area

The president of the Botanical Section, D McClintock, chose as the title of his address "Alien Plants in South-east England" He spoke of the recent introductions and of the probable manner in which they arrived Most were introduced by man, many from the Mediterranean area, then distributed by animals, being carried from place to place in their wool or fur The bomb craters of the War were favourite sites, providing a large number of species *Buddleia* was an outstanding example, being introduced from China as a rather rare plant in 1887, it was widely distributed in the countryside by 1926

Dr R Thurrell, as president of the Geological Section, gave an address on "Aspects of the Geology of the Horsham District" His talk was introductory to the excursion he was conducting during the congress After mentioning that the area was now being examined in detail by the Geological Survey, he outlined the history of its investigation from early times The Romans used Horsham Stone together with hardened clay as the foundation of the Stane Street at Slinfold Iron was obtained from the ironstone in the Hastings Beds up to 1550, later limonite, from the base of the Wadhurst Clay and from the Weald Clay underlying the Horsham Beds, was the basis of the iron industry

Mantell could be regarded as the pioneer of the systematic study of Wealden geology, his discovery of the remains of giant reptiles attracting interest as well as adding considerably to the knowledge of the conditions prevailing at the time of the deposition of the beds The main uses of the Horsham Stone have been for roofing tiles, flag-stones and walls for farm buildings Dr Thurrell concluded by describing the method of capture of minor streams by the River Arun when, on surface examination, there would appear to be more likely directions for their flow.

Miss Joyce Pope addressed the delegates on the upbringing of young animals by human beings Most people liked watching the development of young animals whether they be white mice or gorillas At the onset Miss Pope said she wished to emphasize that both young birds and mammals are around alone before they had finished with parental care and it was a mistake to take them and attempt hand-rearing, for the parents were often close by and would be tending them The exception was with those which had been abandoned or injured, often wished on you by friends Even then the difficulty of the task should be realized and, where recovery seemed hopeless, it would be kinder to dispatch them painlessly Voles were very good pets and when they were in the suckling stage she had found it better to feed with a small paint brush rather than with a fountain pen filler Friendship with a hand-reared animal was apt to end with the animal 'becoming itself', becoming nervous and bad tempered, so one had to prepare it to fend for itself before liberating it in its native habitat Miss Pope then showed the film "Elsa, the Lioness" to illustrate some of the points of her address

Weather conditions, although troublesome, permitted the full excursion programme to be carried out The botanists were conducted by O Buckle on the chalk downs surrounding Chanctonbury Ring, the zoologists visited the secluded parts of St Leonards Forest, under R. M Long's guidance, to study the effects of reafforestation on wild life and to examine the working of the charcoal industry The geological party, numbering seventy, visited the more important outcrops and exposures of the Wealden Series in the Horsham district under the direction of Dr R Thurrell

The excellent arrangements for the congress were undertaken by the Horsham Natural History Society, for whom Mrs R Hurst acted as honorary secretary

F J EPPS

TARONG PYGMIES IN NORTH BURMA

DURING March–April 1962 a team from the Burma Medical Research Society carried out an expedition to the Arumdum area (97° 40′–97° 45′ E, 28° 5′–28° 10′ N) in the Adung Long Valley in the northernmost part of Burma The primary object of the expedition was to study the recently discovered Tarongs—a pygmy tribe living in that area

The team was led by Prof M Mya-Tu of the Department of Physiology, University of Rangoon, other members being Dr. Ko Ko, Dr Aung Than Batu and Dr Kywe Thein of the Directorate of Health, Burma, and Dr C J R Francis and U Than Tun Aung Hlaing of Prof Mya-Tu's Department

The expedition left Rangoon for Putao (Fort Hertz), some 800 miles north, in a Burma Air Force plane From Putao it travelled 60 miles by car until the road ended From there on, it proceeded on foot over mountain, river gorge and valley for nine days until Arumdum was reached

The whole population of Tarongs (69) in that region was examined The team spent seven days in the area during which time it collected anthropometric, hæmatological and other physiological data, and also conducted dietary, goitre and intestinal parasite surveys It also obtained information regarding the customs and beliefs of the Tarongs

Detailed analyses of the results obtained are still in progress, but some preliminary conclusions may be drawn Anthropologically, the Tarongs are of Mongolian stock, and are believed to be ethnologically closest to the Rawangs, a tribe of the Kachins The majority of them are between 4–5 ft in height, very few being taller than 5 ft

The Tarong blood groups show a high predominance of group B with group O coming next No person belonging to group A was found Only two were of group AB Group M was twice as common as MN N was rare Of the Rh group, CDe was most common CDE was also fairly common

Electrophoresis of hæmoglobin solutions, alkaline denaturation test for hæmoglobin F, sickling and osmotic resistance tests were also performed No hæmoglobinopathies were found

Vital registration records are non-existent, but judging from the family-histories, there is a high infant mortality, but once the difficult childhood years are survived, the Tarongs seem to enjoy reasonably good health. There is little evidence of gross malnutrition, and they seem to be relatively free from serious infections like smallpox and plague Intestinal diseases such as dysentery and worm infections also appear to be uncommon As is to be expected in most hill tribes, a high incidence of goitre was evident and, side by side with it cretinism

The team also brought back samples of blood, stool and urine from the Tarongs for further examination, and also collected insects, arrow poisons and medicinal plants from the region for examination in Rangoon

The report of the expedition will be published in the *Proceedings of the Burma Medical Research Society*

AN ELEMENTARY INTERPRETATION OF SCIENCE

IN January 1961, Purnell and Sons, Ltd , printed the first copy of *Knowledge*, a weekly colour journal edited by John Chancellor and an advisory board of Lady Violet Bonham Carter, Prof C N L Brooke, Mr Norman Fisher, Mr Walter Hamilton, Mr John Sparrow, Dr Dudley Stamp and Sir George Thomson The success of this magazine in the field of general education has apparently encouraged the publication of a very similar but more specialized magazine entitled *Understanding Science**, under the senior editorship of Leslie Basford, with a consulting editorial board comprising Sir James Chadwick, Mr Norman Fisher, Sir Harry Melville and Prof J Z Young

According to the chief editor it is "a new weekly magazine intended both for the general public and to help in developing the teaching of Science in schools" The general plan is that each issue will contain a selection of articles, each of which is a member of a series of articles outlining a particular branch of science The first issue, for example, contains articles on biology ("Living Cells"), chemistry ("Atomic Structure of Elements"), electricity ("An Electric Circuit"), heat ("The Fireless Locomotive"), hydrostatics ("Floating and Sinking"), magnetism ("The 'Loves' and 'Hates' of Magnets") and technology ("Using a Micrometer"), as well as an article on Sir Isaac Newton The cover design and article printed on the front and back constitute a special feature on topics of general scientific interest the first of these is entitled "Water and Life on Earth" Every twelfth issue will contain an index and title-page to facilitate collecting and binding of the copies· this habit will be further encouraged by the offer of special volume binders both for the main articles and for the special features

The text is very clearly printed, and on the whole the large diagrams and illustrations are good The sections on the micrometer (issue No 1, pp 8–9), the chemical balance (No 2, pp 24–25) and the microscope (No 3, pp 42–43) which would, as Mr Basford suggests, provide science teachers with material for visual aids, are quite impressive On the other hand, some of the biological drawings such as the worm, flowering plant and *Spirogyra* (No 1, pp 10–11) and the plankton (No 4, pp 56–57) are rather poor Some of the material and illustrations are taken directly from the *Junior Science Encyclopaedia* (Sampson Low, Marston and Co , Ltd) The topics are always treated as clearly and as simply as possible Occasionally, therefore, they suffer the inevitable consequences of oversimplification and contain somewhat misleading statements such as "Atoms are the smallest possible pieces of the basic pure materials that make the universe" (No 1, p 5) and "At another certain temperature water turns into a gas—steam On the centigrade scale of temperature the point at which this happens is defined as 100°" (No 1, back cover)

The editor claims that the magazine will present science in a way which is easy to understand He also claims that it will cover the equivalent of the Ordinary Level syllabus of General Certificate of Education in chemistry, physics, biology, etc Unfortunately, he does not indicate how many years this will take Nevertheless, the parents of young aspiring scientists may, perhaps, still consider 2*s* every Monday a worth-while investment.

MICHAEL C COX

---

* *Understanding Science*, No 1 (A New Colour Magazine which becomes an Encyclopedia) Pp 16 Subscription rates 52 weekly copies, £6 10*s* 0*d* , 26 weekly copies, £3 5*s* 0*d* (Paulton, Nr Bristol Purnell and Sons Ltd , 1962)

U.S. COMMITTEE ON EXTENSION TO THE STANDARD ATMOSPHERE*

A REVISED *U.S. Standard Atmosphere to 700 km* is about to be adopted by twenty-nine U.S. scientific and engineering organizations, the U.S. Committee on Extension to the Standard Atmosphere (COESA). This Committee has also recommended the lower 32 km of this representation of the atmosphere to the International Civil Aviation Organization (ICAO) for international standardization. The lowest 20 km of this new COESA atmosphere coincides with the current 20 km ICAO Standard Atmosphere except for minor differences due to revised standardization of some physical constants. The new COESA atmosphere is in general agreement with the Committee on Space Research International Reference Atmosphere (CIRA) 1961, but follows the rules established for the previous U.S. and current ICAO Standard Atmospheres, and will provide more detail and more parameters than CIRA. It includes refinements, in matching the data, which were not possible in the earlier COSPAR report. Fortunately, continued scientific communication between COSPAR and COESA reduced discrepancies between the two atmospheres to a minimum.

The complete report, including tables, of the revised atmosphere is being prepared for U.S. Government publication to replace the *U.S. Extension to the ICAO Standard Atmosphere—Tables and Data to 300 Standard Geopotential Km* (G.P.O., Washington, D.C., 1958).

The National Aeronautics and Space Administration (NASA), the Geophysics Research Directorate, Air Force Cambridge Research Laboratories, and the U.S. Weather Bureau jointly sponsored the movement which led to this new representation of the atmosphere. Participating organizations included Aeronautical Systems Division, AFSC, Air Force Deputy Commander Aerospace Systems, AFSC, Air Weather Service, Applied Physics Laboratory (Johns Hopkins University), Army Ballistic Missiles Agency, Army Signal Research and Development Laboratory, Ballistics Research Laboratory (Aberdeen Proving Grounds), Battelle Memorial Institute, The Boeing Co., Federal Aviation Agency, General Dynamics, Geophysics Corporation of America, Geophysics Research Directorate, AFCRL, Goddard Space Flight Center, NASA, Harvard College and Smithsonian Astrophysical Observatory, High Altitude Engineering Laboratory (University of Michigan), Jet Propulsion Laboratory (California Institute of Technology), Langley Research Center, NASA, Lockheed Missile and Space Co., Marshall Space Flight Center, NASA, NASA Headquarters, National Bureau of Standards, Naval Proving Grounds, Naval Research Laboratory, Navy Weather Research Facility, The Rand Corporation, Space Technology Laboratories, Inc., Weather Bureau, Department of Commerce, White Sands Missile Range.

COESA is an unofficial group of scientific and engineering organizations, each holding national responsibilities related to the requirement for accurate tables of the atmosphere to high altitudes. They joined forces toward developing such an atmosphere in November 1953. Several new organizations have since been added to the ranks. A working group, appointed at the first meeting, met frequently between 1953 and the end of 1956, at which time the entire committee accepted their recommendations, published by the G.P.O. in 1958.

Scientific progress could scarcely wait for the publications of this 1958 document, when orbital periods of the first *Sputnik* indicated that densities at the upper altitudes were of more than an order of magnitude. A new Working Group was convened in January 1960 to review all available satellite and rocket data as related to the COESA table and to consider the need for revision. It recommended, on an interim basis, the ARDC 1959 Model Atmosphere, GRD, AFCRC-TR-59-267, August 1959. Up to about 50 km this atmosphere was the same as the recently published U.S. extension to the ICAO Standard Atmosphere. Above that altitude some International Geophysical Year rocket and early satellite data were used. Since all these data were obtained during the period of maximum solar activity, the resulting model was more representative of these conditions than

Z = geometric altitude h = geopotential altitude

T = kinetic temperature M = mean molecular weight.

L = gradient of molecular scale temperature = $\mathrm{d}T_M/\mathrm{d}h$ (below 79 geop km).
= $\mathrm{d}T_M/\mathrm{d}Z$ (above 79 geop km)

T_M = molecular scale temperature = $(T/M)\,M_0$

M_0 = sea-level value of M.

average atmospheric properties For the next year, the Working Group studied new data and theories from more refined satellite flights Greater confidence was required than could be obtained using U S S R satellite orbital periods, since the U S S R aerodynamic configurations were not accurately known A few years of observations at satellite altitudes were also required to understand the effects of solar activity and position The American satellites provided the necessary extreme altitude data Additional rocket flights provided needed detail for levels above those of balloon flights The COESA Working Group prepared a recommendation from this new scientific inventory which was accepted by the entire committee on March 15, 1962

The *Revised U S Standard Atmosphere* will depict typical mid-latitude year-round conditions averaged for daylight hours and for the range of solar activity which occurs between sunspot minimum and sunspot maximum Supplementary presentations will also be provided to indicate variability of density above 200 km with solar position

The new atmosphere is defined by linear-segmented temperature–height relationship (Fig 1) The last COESA standard is included for comparative reasons The terminology of 'standard' in the figure was applied to the layer of the atmosphere in which it is believed there will be international agreement established by the ICAO The next layer covers an altitude interval much explored by rocketry, yet subject to some modification in order to be consistent with the revisions of the atmosphere above 90 km , which are certain to be required as more data become available The speculative altitude interval 90–700 km is, of course, a zone about which there is still much to learn

Although density is the primary atmospheric property measured at, or deduced for, very high altitudes, it was necessary to define the atmosphere in terms of temperature, in order that the extension above ICAO levels be continuous with the ICAO atmosphere Temperature segments at higher altitudes, developed from the barometric equations, are consistent with observed density data The basic framework for the extensive tables of the *U.S Standard Atmosphere, 1962*, which will be published through the G P O , appears in skeleton form in Table 1 The completed tables will follow closely the format developed in the Committee's *1958 Standard Atmosphere*

COESA is also developing a set of supplemental atmospheres which will represent mean summer and winter conditions by 15 deg latitude intervals from the tropics to the poles to an altitude of 90 km These atmospheres will appear some time later as an appendix to the revised *U S Standard Atmosphere*

The final report will be prepared for publication by NASA, under the monitorship of a three-man editorial board, representing each of the co-sponsoring organizations The published volume will not be part of any existing series but a separate publication of the U S Government Co-sponsors and all organizations of the Parent Committee will be prominently indicated, as will the editors and contributing scientists and engineers Much of the work to date has been accomplished by four Task Groups, into which the Working Group was divided to provide recommendations for various altitude intervals

The preparation of the *Tables* and final report will be under the supervision of Mr William J O'Sullivan, Langley Research Center, National Aeronautics and Space Administration, assisted by Mr Richard Hord Mr O'Sullivan and Dr K S W Champion, Geophysics Research Directorate, Air Force Cambridge Research Laboratories, assisted by Dr Hartley Pond, and Mr Sidney Teweles, U S Weather Bureau, will be principal editors

CABOT FAULT, AN APPALACHIAN EQUIVALENT OF THE SAN ANDREAS AND GREAT GLEN FAULTS AND SOME IMPLICATIONS FOR CONTINENTAL DISPLACEMENT

By Prof. TUZO WILSON, O.B.E.

Institute of Earth Science, University of Toronto

The Cabot Fault, its Trace and Age

FROM northern Newfoundland across Nova Scotia and the Bay of Fundy to Massachusetts and Rhode Island there extends a narrow belt of large faults. Although all parts are well documented, little attention has been paid to the apparent continuity of this dislocation which in its entirety will be called the Cabot fault after the strait it crosses.

In Newfoundland, the Cabot fault (Fig. 1) forms the east side of the Northern Peninsula[1] at the southern end of which it bifurcates into several subparallel branches in the valley containing Deer and Grand Lakes[2–9]. Thence it crosses to the south-west corner of the island[2,10–12].

H. L. Cameron has suggested that the fault crosses Cabot Strait[13,14], a view supported by the strike of anomalies on aeromagnetic maps[15], and that it continues across Nova Scotia. In northern Cape Breton Island[16] and across the isthmus from Cape George to Cape Chignecto[17–20] faults are clearly mapped, but in southern Cape Breton the published maps[21–25] disagree and Cameron has also suggested privately that the main fault may lie off the west coast of Cape Breton. If so, its extension may cross the isthmus farther west under cover of a deep basin of Pennsylvanian and Permian rocks[26]. From Cape Chignecto anomalies shown on aeromagnetic maps[27] and an observation by S. Powers[28] suggest that the fault connects across the Bay of Fundy with one postulated by P. B. King[29] to lie off the New Brunswick coast. D. W. Johnson[30] has suggested that faults which appear to form "one of the great fracture lines of North America" continue across the Gulf of Maine to Massachusetts. Recent seismic measurements barely intersect the fault, and are said to provide no basis for any conclusions about it[31]. This zone strikes the coast where five basins of late Palæozoic rocks and many large faults cross Massachusetts and Rhode Island. Extensive glacial cover, complex structure, lack of continuous marker horizons and few fossils have made this a difficult region to map so that a variety of views has been expressed, but recent ones involve large faults striking south-west[32–36]. Without attempting to resolve these ambiguities, this much is sufficient to suggest that a late Palæozoic fault zone does reach this vicinity.

Members of the committee preparing a new tectonic map of Canada have stated that in uppermost Devonian time a phase of deformation began in the Canadian Appalachians which was "restricted to a narrow belt which extends from the Bay of Fundy through Cape Breton Island north-east to Cape Anguille and beyond to White Bay, Newfoundland. Folding of the Carboniferous rocks varied in time and intensity from place to place within this belt. It was chiefly controlled by movements of rigid blocks of pre-Carboniferous rocks. Late Pennsylvanian (Pictou) sediments and block-faulted Triassic red beds and basic volcanics cover strata of this late Palæozoic folded belt"[37]. This description also seems valid for the southern part of the belt, although there is disagreement about the precise age of the basins in New England.

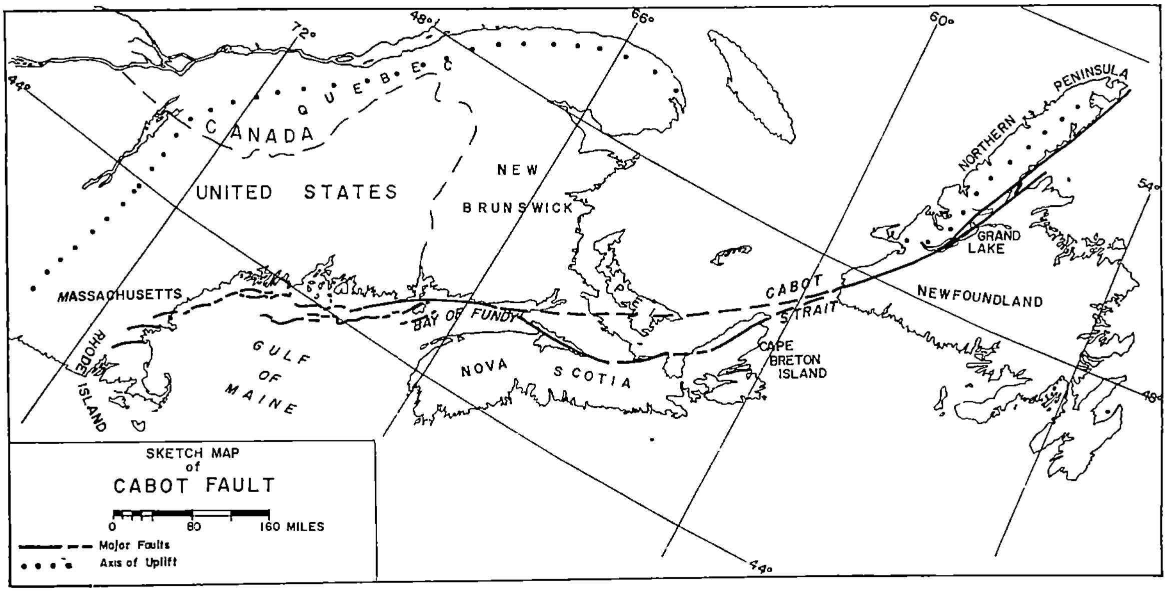

Fig. 1. Sketch map of the Cabot fault

Comparison between the Cabot and San Andreas Faults

Detailed study shows that this deformation conforms to the characteristics used by Hill and Dibblee[38,39] to suggest that the San Andreas rift is a great transcurrent fault. These include (1) long sections of straight trace, (2) steep but variable dips, (3) a disturbed zone varying from a few feet to a few miles in width, (4) apparent reversals in throw along the fault, (5) local drag folds and thrusts across it, (6) profound differences in older rocks on opposite sides of the fault.

It has therefore been suggested that the Cabot fault is a great transcurrent fault similar to the San Andreas[40], but active in late Palæozoic time. It will be observed that both faults formed late in their respective orogenies and that both occupy similar geographical and tectonic positions relative to the continent and the mountain belts.

It is tempting to go further and to compare the Bay of Fundy and the Gulf of Maine with the Gulf of California, but this is premature, for the crust beneath the Gulf of California is oceanic[41], whereas that beneath the Gulf of Maine is transitional between continental and oceanic[31] and the displacement on the Cabot fault is unknown. It is more justifiable to point out that the fault cuts like a bow-string across the curve of the Appalachians in New England and southern Quebec.

An anorthosite body in south-western Newfoundland of which the offset part does not re-appear within the region which has been mapped might suggest a minimum lateral displacement of more than 80 miles, whether dextral or sinistral, but officers of the Geological Survey now feel that this fault, along much of its trace, forms a complete separation between pre-Cambrian and younger basement complexes. If the branch faults[4,9] which turn off to the east from Grand Lake to Notre Dame Bay are due to 'horsetailing' their orientation suggests a sinistral displacement. If the large, younger transcurrent faults of post-Triassic age recently reported in New Jersey[42] should prove to be related to the Cabot fault, then their north–south strike and dextral motion would suggest a conjugate relation.

Comparison between the Cabot and Great Glen Faults

Most reconstructions of the continents based on the assumption of continental drift bring Newfoundland into juxtaposition with the British Isles[43,44].

On any such map it will immediately be seen that the Cabot and Great Glen faults[45] are opposite to one another and have the same orientation. Since both are the same age (uppermost Devonian and Lower Carboniferous), are transcurrent, are large, are perhaps sinistral and cut rocks well known to be similar[46,47], it is reasonable to speculate that, if drift has occurred, they are two ends of the same fault. It follows that the Lewisian might have been part of the Labrador province[48,49] and the granodiorite stocks in north-eastern Newfoundland such as those in the Bay of Exploits[50] and Fogo Island[51] might be other volcanic centres of the Ben Nevis type[52,53], for they are of the same age and composition and can be seen to have swarms of narrow, pink-weathering, acid dikes striking north-east from the centres.

Acceptability of Continental Drift

When the theory of continental drift was first proposed it was supported by the parallelism of some adjacent coasts on opposite sides of oceans and by the faunal, structural and stratigraphic coincidences which would result if these coasts had once been in contact[43]. Opponents pointed out that to have fitted more than a few coasts together would have required unacceptable distortions of the continents. They felt that, in fauna, coincidences could be explained by migration, in structure, by mountain chains crossing oceans, and in stratigraphy, by the same reasons plus climatic similarities[44,47]. Most physicists[54] considered that the crust of the Earth was too strong and the interior too viscous for continents to have been moved by the proposed dynamic forces.

In spite of these objections, evidence supporting drift has continued to accumulate. Some aspects are of new kinds like that from palæomagnetism[55] and that of transcurrent motions of more than 1,400 km. on the Pacific Ocean floor[56], but some concern closer geological relations[57]. If to the generalized suggestions of fit formerly advanced could be added several precise structural relationships, then coincidence would become too improbable an explanation and drift would have to be accepted. The continuation of the Moine thrust, if it could be traced in western Newfoundland, might provide another connexion like that just discussed.

The discovery[58–60] of a low velocity layer at a depth of 100–200 km. in the upper mantle has provided a possible lubricating channel on which the crust may move. Arguments have been advanced that in some places the crust has developed weak zones along which it can break far more easily than had been supposed[61]. Three further points may make drift more acceptable.

First, it would seem that the proponents of drift did their cause great harm by their too rigid concepts of the proto-continents of Pangaea or Laurasia. If, instead of believing that the present continents had all been confined in neat packets before Carboniferous time, they had assumed that continents and fragments of continents had always had a random distribution and motion, now joining together in one place and now rifting and separating elsewhere, they could have explained the good fits of some coasts without the necessity of introducing any hypothetical and unnecessary distortions[62]. If they had considered that continents may grow along their leading edges[63] they could have explained why coasts which may once have fitted together are now so altered by growth that the fit is no longer obvious.

It may be that the crust breaks and moves as a result of dynamical forces, but my second point arises if alternatively the crust is considered to move because of convection currents in the mantle[64]

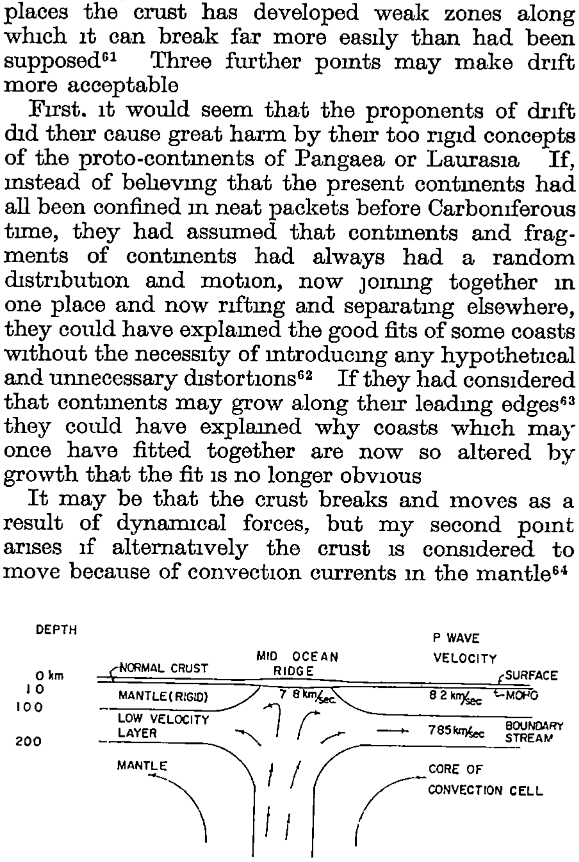

Fig. 2. Section across a mid-ocean ridge suggesting one possible underlying structure

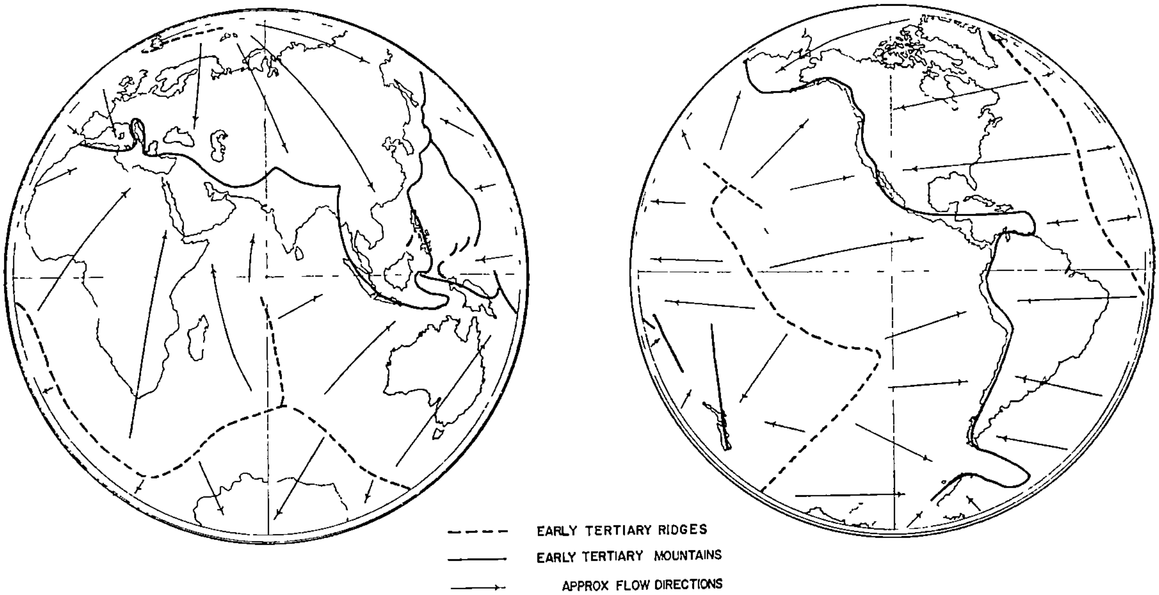

---- EARLY TERTIARY RIDGES
—— EARLY TERTIARY MOUNTAINS
—→ APPROX FLOW DIRECTIONS

Fig 3 World map of continental and mid-ocean mountain systems in early Tertiary time showing directions in which sub-crustal currents may have moved

If there is convective overturn it is presumably driven by relatively narrow streams of heated matter rising along the boundaries between cells If these cells behave as in other convecting systems the cores can be presumed to turn over rather as though they were solid rollers, the adjustment to the boundaries being confined to narrow peripheral streams Hence, following the usual assumption that the currents rise under the mid-ocean ridges, we might suppose that, as the rising convection currents approach the surface, adjustments between them and the cooler and more brittle uppermost layers of the mantle and crust would take place in a comparatively thin sub-surface layer Such adjustments are to be expected because the uppermost layers are cool and presumably withstand stress differences over longer periods of time than does the interior The segments of the uppermost layer may move at different velocities from the currents beneath them If so, it is reasonable to ask whether the zone of adjustment is not connected with the low velocity layer Fig 2 illustrates why, under the mid-ocean ridges[65], the velocities immediately beneath the Mohorovičić discontinuity might be about equal to those in the low velocity layer elsewhere[59,60]

Thirdly, in spite of the difficulty just mentioned, if convection currents are supposed to rise under mid-ocean ridges and sink under continental mountains, the location of the systems is known and the approximate flow-pattern can be plotted on a globe[66] One possible pattern for early Tertiary time has been plotted in Fig 3 and it will be noticed that the whole surface of the Earth is involved in a pattern separated by the two continuous lines of mountains and ridges respectively The whole mantle can be thought of as behaving as a single, continuous torus twisted about the Earth and rotating in a uniform direction, although different segments may have moved at different rates producing differential motions in the crust above the segments[56]

The possible pattern from early Tertiary time was chosen because at that time the pattern was straightforward Since then a change has been supposed to have occurred in the Pacific[67,68] It is confusing because it has superimposed the supposedly rising current of the East Pacific Rise on the sinking current postulated for the Cordillera A complexity has also arisen in East Africa

While considering convection currents, R Hyde demonstrated by a model that the currents between two rotating cylinders tended to follow one stable mode or pattern until the thermal conditions were changed sufficiently to cause the currents to change abruptly to some other mode

If there are convection currents in the mantle and they behave in a similar manner, we might suppose that changes in the thermal state of the Earth have from time to time produced changes in mode, each of which has corresponded to one major, world-wide orogenic cycle and that the intervening periods of stable modes have corresponded with times of fixed patterns of mountain building[69]. The irregularities mentioned suggest that such a change may now be starting

It is also easy to see that currents rising and diverging will rarely produce longitudinal shears along the mid-ocean ridges whereas converging currents approaching the continental mountains from different directions might produce shear faults along the mountain belts of which the Cabot fault may be one of many examples

I thank Prof A F Pillow for advice on the behaviour of convection currents, and Drs D M Baird, D G Kelley, E R W Neale and G C Riley for information about the geology of eastern Canada

DEFORMATION OF URANIUM DURING ALPHA/BETA CYCLES UNDER SMALL STRESSES AND A QUANTITATIVE INTERPRETATION OF THE MECHANICAL WEAKNESS OF METALS UNDERGOING PHASE TRANSFORMATIONS

By Dr R. H. JOHNSON and Dr G. W GREENWOOD

Central Electricity Generating Board, Materials Division, Berkeley Nuclear Laboratories, Gloucestershire

THOUGH the mechanical weakness of metals when undergoing phase transformations is well known, no analyses have been developed which explain the extent of deformation occurring when small stresses are applied We have examined this phenomenon experimentally for the case of α/β cycling of uranium, and propose a quantitative theory to explain our results and the observations of other workers on other metals, notably iron

Specimens of pure (Springfields Dingot) uranium 0 025 cm thick, 1 cm wide and 2 cm in gauge-length were subjected to tensile stresses in the range 24–430 gm /mm ^{2} while undergoing α/β cycles at a rate of 3 cycles/hr about a temperature-range of 665° ± 50° C The specimens were situated in the centre of a vertical furnace and the thermal flux was approximately perpendicular to the applied stress The deformation was measured continuously and after the first one or two cycles the elongation per complete cycle ($\alpha \rightarrow \beta \rightarrow \alpha$) was constant for a given load The strain per cycle increased with applied stress as illustrated in Fig 1 Such a linear relationship has already been noted in the case of $\alpha \rightarrow \gamma \rightarrow \alpha$ cycles for iron[1]

It is suggested here that our results for uranium and those obtained for iron can be explained quantitatively by a development of recent theoretical models[2,3] of the deformation which occurs when a material is highly stressed internally and is subjected to a small external stress In the case of uranium, the first region which transforms into the β-phase increases in volume by an amount $\frac{\Delta V}{V}$ Since this phase is considerably harder than the α-phase, the latter deforms plastically Assuming that plastic deformation can be considered exclusive to the α-phase, its mode of deformation can be described by the matrix·

$$\begin{bmatrix} \left(\frac{\Delta V}{V}\right)_x & 0 & 0 \\ 0 & \left(\frac{\Delta V}{V}\right)_y & 0 \\ 0 & 0 & \left(\frac{\Delta V}{V}\right)_z \end{bmatrix}$$

where $\left(\frac{\Delta V}{V}\right)_x$, etc , are the components of plastic deformation in the x, y and z directions respectively and ΔV is the volume difference between the α- and β-phases If a small stress σ is applied in the z direction, and an increment of plastic strain ε occurs for each $\alpha \rightarrow \beta$ transformation, then the deformation matrix is expressed as

$$\begin{bmatrix} -\varepsilon/2 & 0 & 0 \\ 0 & -\varepsilon/2 & 0 \\ 0 & 0 & \varepsilon \end{bmatrix}$$

Making the assumptions that each grain undergoes the same average strain as the aggregate and that the deformation obeys the Lévy–von Mises criterion, then

$$\left[-\varepsilon/2 - \left(\frac{\Delta V}{V}\right)_x\right]^2 + \left[-\varepsilon/2 - \left(\frac{\Delta V}{V}\right)_y\right]^2 + \left[\varepsilon - \left(\frac{\Delta V}{V}\right)_z\right]^2 = \frac{2}{3}\lambda^2 Y^2$$

where Y is the yield stress of the α-phase at the transformation temperature and λ is a constant Now

$$\sigma = 3/2\lambda\left[\varepsilon - \left(\frac{\Delta V}{V}\right)_z\right]$$

so that λ can be eliminated from the two equations, and for the condition that $\varepsilon < \frac{\Delta V}{V}$, we obtain a strain for each α/β cycle given by

$$\varepsilon \sim \sqrt{\frac{2}{3}}\,\frac{\sigma}{Y}\left[\left(\frac{\Delta V}{V}\right)_x^2 + \left(\frac{\Delta V}{V}\right)_y^2 + \left(\frac{\Delta V}{V}\right)_z^2\right]^{\frac{1}{2}} + \left(\frac{\Delta V}{V}\right)_z$$

Now

$$\left(\frac{\Delta V}{V}\right)_x^2 + \left(\frac{\Delta V}{V}\right)_y^2 + \left(\frac{\Delta V}{V}\right)_z^2$$

is invariant and can be shown to have the value $\frac{2}{3}\left(\frac{\Delta V}{V}\right)^2$ This implies that the effect of the applied stress is to give an increment of deformation for each transformation which is independent of the orientation of the phase front and the direction in which it moves The term $\left(\frac{\Delta V}{V}\right)_z$ represents the component of the strain which occurs in the direction of measurement due to the change in volume alone and depends strongly on the shape of the transformation front It has been shown[4] that this term need not be zero for a complete transformation cycle $\alpha \rightarrow \beta \rightarrow \alpha$, and in the extreme case[5] of a plane transformation front of constant orientation it can approach a value $\sim \frac{\Delta V}{V}$. Representing the component of strain due to the change in volume alone by $\left(\frac{\Delta V}{V}\right)_T$ for a complete $\alpha \rightarrow \beta \rightarrow \alpha$ cycle, the total deformation ε_n after n complete cycles is given by

$$\frac{\varepsilon_n}{n} \sim \frac{4}{3}\,\frac{\sigma}{Y}\,\frac{\Delta V}{V} + \left(\frac{\Delta V}{V}\right)_T \qquad (1)$$

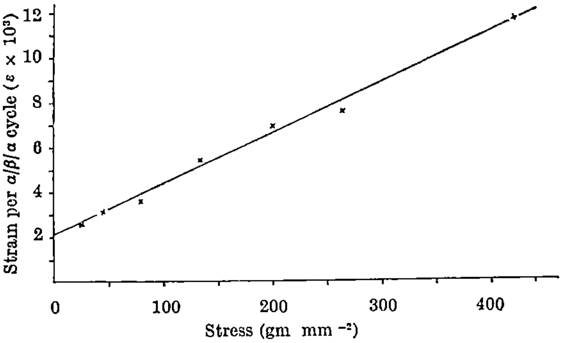

Fig 1

From equation (1) and the experimental results in Fig 1 the value of Y, the yield stress of the α-phase at the transformation temperature, is deduced to be 600 gm /mm ², which is similar to the experimentally measured yield stress on our material There is thus close correlation between theory and experiment

We have also compared equation (1) with experimental results on iron[5] Here work on material with 0 008 wt per cent nitrogen and with 0 2 wt per cent carbon has been reported with values of the yield stresses of these materials at the transformation temperature of 1,000 and 2,000 gm /mm ² respectively These values are in reasonable agreement with values of 600 and 1,200 gm /mm ² respectively, deduced from equation (1)

The intercept in Fig 1 which corresponds to the extent of deformation without applied stress must now be compared with equation (1), where it is identified with the term $\left(\frac{\Delta V}{V}\right)_T$ We find $\left(\frac{\Delta V}{V}\right)_T \sim 0\ 2\left(\frac{\Delta V}{V}\right)$ This is roughly comparable with values generally less than 0 3 $\left(\frac{\Delta V}{V}\right)$ on cycling without applied load[4] Such values, however, are extremely sensitive to the shape of the transformation front and $\left|\left(\frac{\Delta V}{V}\right)_T\right|$ is likely to be a small fraction of $\frac{\Delta V}{V}$ unless the conditions are such that the transformation front remains plane and of constant orientation

We conclude that the strain ε_n occurring after n complete cycles under small applied stress σ can be described by an equation of the form

$$\frac{\varepsilon_n}{n} = A\,\frac{\sigma}{Y}\left(\frac{\Delta V}{V}\right) + B\left(\frac{\Delta V}{V}\right)$$

where Y is the yield stress of the phase which deforms plastically A is independent of and B is very sensitive to the orientation of the phase front Both theory and experiment lead to the values $A \sim 4/3$ and $|B| < 1$

ELECTRON MICROSCOPY AT HIGH BEAM ACCELERATING VOLTAGES

By DR. R. E. BURGE and G. H. SMITH

Department of Biophysics and Medical Research Council Biophysics Research Unit,
King's College, University of London, Strand, W.C.2

THE practical aspects of electron microscopy at beam accelerating voltages in the range 300–1,000 kilovolts (kV.) have recently been given a good deal of attention. The French machine was the first to yield results[1-3] in this voltage-range, and other similar projects are being developed in a number of countries and at the Cavendish Laboratory, Cambridge. The theory of the contrast expected in the images of biological specimens and in the images of amorphous specimens in general has not, however, received so much attention. A few calculated values, at 500 and 1,000 kV., of the electron-scattering cross-sections for a number of elements as functions of angle of scattering have been published by us[4] and it is proposed to extend these data here. Since at high voltage it is the hope that thick specimens may be examined under conditions of adequate image contrast, clearly the two factors, penetration and contrast, must be considered together.

The contrast, C, in the image of a specimen of mass-thickness $\omega(\omega = \rho t$ where the specimen is of density ρ and thickness $t)$ is given by the equations

$$C = \ln I_0/I = S_t\omega = (S_e + S_i)\omega \qquad (1)$$

Here the incident intensity I_0 of the electron beam is reduced to I by the scattering of electrons by the specimen at angles greater than the semi-angular aperture α of the objective lens. The total mass-scattering cross-section of the amorphous specimen for scattering outside α is S_t, S_t represents the sum of the elastic and inelastic scattering components S_e and S_i. When $\alpha = 0$, S_t becomes S_T, the total mass-scattering cross-section for scattering at all angles, also S_e and S_i become respectively S_E and S_I under this condition.

It has been shown both theoretically and by experiment[4] that, at voltages in the 50–100 kV. range, S is virtually independent of the composition of the specimen. For a given specimen examined at constant α, S decreases as the accelerating voltage increases, whereas, at a given accelerating voltage, S decreases as α increases. Thus, to maintain the highest possible level of contrast in the image at high accelerating voltages α must be made as small as possible. The smallest value of α is limited ultimately by diffraction effects and the astigmatism in the image caused by the rapid contamination of small objective-lens apertures in the electron beam.

On theoretical grounds, S (equation 1) is expected to remain constant under single scattering conditions, that is, provided specimens are of a mass-thickness such that, on the average, each electron is not scattered more than once. Multiple scattering sets in for mass-thicknesses greater than a certain value—the critical mass-thickness, $\omega_{\lim}$. Now $\omega_{\lim}$ may be defined in two ways[5] according to whether elastic scattering only or total scattering is considered. It is proposed to use both definitions of $\omega_{\lim}$, that is, $\omega_{\lim} = 1/S_e$, $1/S_t$; when $\alpha = 0$ then $\omega_{\lim}$ is expressed[5] as $1/S_E$ and $1/S_T$. Thus, $\omega_{\lim}$ gives a measure of (a) the contrast in the image which may be ascribed to either elastic or total electron scattering for a given specimen examined at a given beam accelerating voltage and a given value of α, (b) the penetration of electrons in amorphous specimens under single scattering conditions.

The theory used in the calculations is that published by us[4], which essentially represents a redevelopment of the Lenz[6] single-scattering theory on the basis of recently published theoretical descriptions of the atom. Calculations with full relativistic corrections were made for the elements carbon and gold. These two elements were chosen in order to approximate the electron scattering by organic specimens (carbon, oxygen and nitrogen are very similar) and to give an example of an element of high atomic number (gold). Three apertures were chosen, $\alpha = 0$ (a purely theoretical case corresponding to conditions of maximum contrast), $\alpha = 10^{-3}$ radian, and $\alpha = 5 \times 10^{-3}$ radian. The variations of $\omega_{\lim}$, on the definitions already given, and for beam accelerating voltages up to 1,000 kV., are shown in Figs. 1–3.

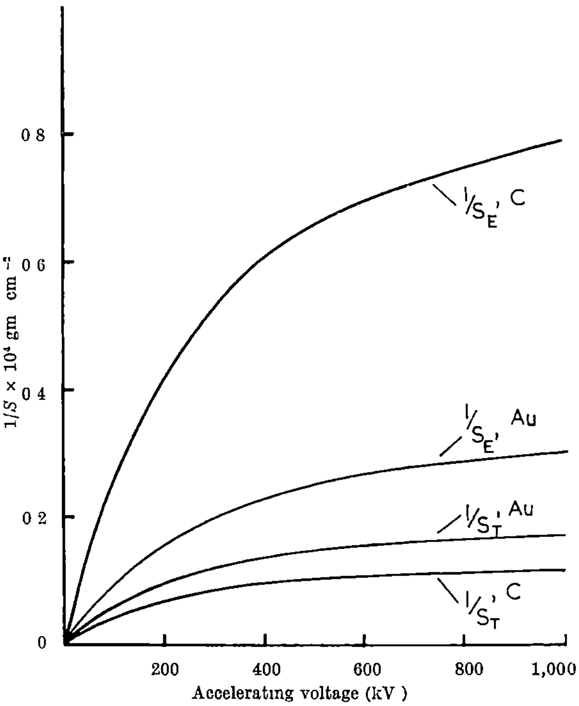

Fig. 1. The variation of $\omega_{\lim}$ (= $1/S$) with accelerating voltage for carbon and gold, $\alpha = 0$

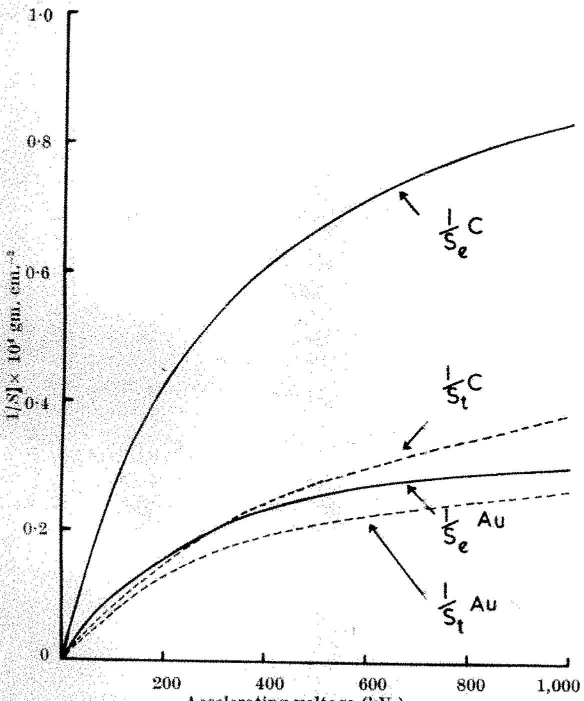

Fig. 2. The variation of ω_{lim} ($= 1/S$) with accelerating voltage for carbon and gold; $\alpha = 10^{-3}$ radian

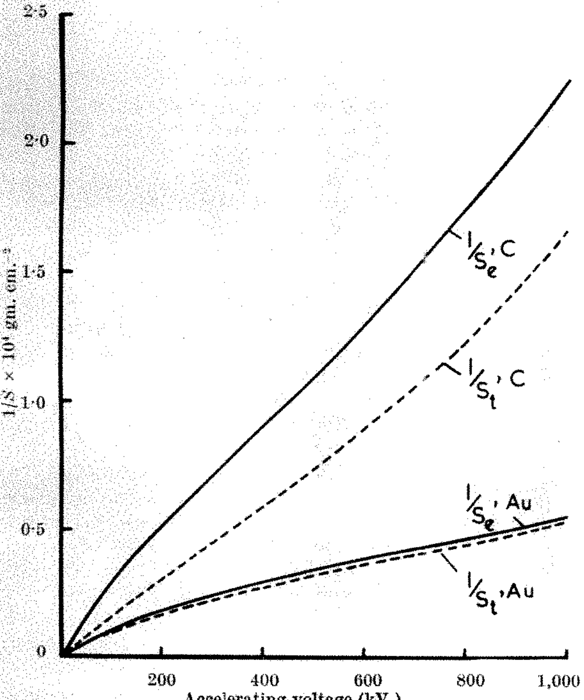

Fig. 3. The variation of ω_{lim} ($= 1/S$) with accelerating voltage for carbon and gold; $\alpha = 5 \times 10^{-3}$ radian

To interpret these curves in terms of a critical specimen thickness t_{lim} ($\omega_{\text{lim}} = \rho t_{\text{lim}}$) the densities of amorphous carbon and of gold should be used; these values are about 2 and 20 gm. cm.$^{-3}$ respectively.

It is clear from Figs. 1–3 that an assessment of the dependence on accelerating voltage of the electron penetration under single scattering conditions depends critically on the angular aperture of the objective lens. Fig. 1 ($\alpha = 0$) shows that the limiting thicknesses tend to constant values above an accelerating voltage of about 500 kV. Fig. 2 ($\alpha = 10^{-3}$ radian) shows that all the values of ω_{lim} increase fairly slowly with increasing accelerating voltage above 500 kV., while in Fig. 3 ($\alpha = 5 \times 10^{-3}$ radian) the values of ω_{lim} increase fairly rapidly with increase of accelerating voltage over the entire range.

Thus, at very small objective apertures ($\alpha <$ say 10^{-3} radian), corresponding to relatively high image contrast, the increase in ω_{lim} with accelerating voltage above, say, 500 kV. is scarcely worth while. However, for $\alpha > 10^{-3}$ radian, where image contrast is lower, ω_{lim} increases with increasing voltage over the entire range considered; the larger the value of α the faster ω_{lim} increases with increase of voltage.

In Table 1 are given some examples of the calculated values of t_{lim} at 100 kV. and 1,000 kV.

Table 1. VALUE OF t_{lim}

Definition	Voltage (kV.)	t_{lim} Å. (carbon)	t_{lim} Å. (gold)
$1/S_T$	1,000	596	86
$1/S_T$	100	225	31
$1/S_t$ ($\alpha = 10^{-3}$ radian)	1,000	1,920	132
$1/S_t$ ($\alpha = 10^{-3}$ radian)	100	420	38
$1/S_t$ ($\alpha = 5 \times 10^{-3}$ radian)	1,000	8,325	263
$1/S_t$ ($\alpha = 5 \times 10^{-3}$ radian)	100	823	48

Although these theoretical results may be in error, it is a reasonable assumption that the qualitative agreement between theory and experiment found at accelerating voltages below 100 kV. (ref. 4) will extend to higher voltages. It appears therefore that, for amorphous specimens in general and for biological specimens in particular, examined in the electron microscope with objective apertures which are not too small ($\alpha \nless$ say 10^{-3} radian), ω_{lim} increases in a favourable manner with increase of accelerating voltage up to 1,000 kV. Since the increased penetration is at the expense of image contrast, electron-staining techniques to increase contrast should be especially valuable at very high voltages.

It should be noted that the rate of change of S_t with voltage for finite apertures (Figs. 2 and 3) depends on the element concerned and increases with increase in size of the objective aperture; substance differentiation may be possible by this means. The rough constancy of S_t with atomic number found at voltages in the 50–100 kV. range evidently does not extend to higher voltages.

Although thicker specimens than those useful at accelerating voltages up to 100 kV. may be used with benefit at very high voltages, presumably the resolution in the recorded image will be limited to 1/10th–1/20th of the specimen thickness[7,8].

We thank Prof. J. T. Randall for facilities and advice, Dr. V. E. Cosslett for discussion, and the University of London Computer Unit for the use of the digital computer *Mercury*. One of us (G. H. S.) is indebted to the Medical Research Council for a research scholarship.

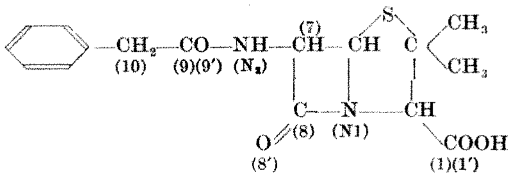
A STRUCTURAL SIMILARITY BETWEEN N-ACETYLMURAMIC ACID AND PENICILLIN AS A BASIS FOR ANTIBIOTIC ACTION

By J. F. COLLINS and M. H. RICHMOND

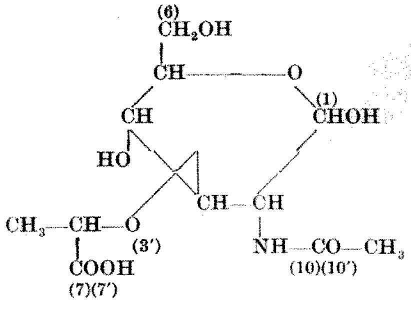
National Institute for Medical Research, Mill Hill, London, N.W.7

THERE is considerable evidence supporting the idea that the antibiotic activity of penicillin is connected with the presence of *N*-acetylmuramic acid in the mucopeptide of bacterial and rickettsial cell walls, and that the antibiotic acts in sensitive strains by interfering with the function of an enzyme which normally handles some derivative of *N*-acetylmuramic acid as an intermediate during mucopeptide synthesis[1-5]. Inhibition of this type could occur if penicillin were bound to the part of the active centre that normally handles the *N*-acetylmuramic acid residue of the intermediate. To do this, the binding groups in penicillin must be able to form bonds to the active centre similar to some of those which bind the *N*-acetylmuramic acid residue.

To see whether *N*-acetylmuramic acid and penicillin showed any similarity in this respect, wire models of the two molecules were constructed to a scale of 2·5 cm./Å. Penicillin (I) was made in its correct absolute configuration[6], and *N*-acetylmuramic acid (3-*O*-D-α-carboxyethyl-*N*-acetyl-D-glucosamine[7]) (II), being derived from D-glucose, was constructed from crystallographic data for D-glucose, *N*-methylacetamide and D-tartaric acid[8]. *N*-Acetylmuramic acid is not a rigid molecule, and the configuration considered here is not the most stable, but one which could occur on the active site of an enzyme. Penicillin, in contrast, has a rigid configuration across both rings in the nucleus. There is restricted rotation about the bond C_7–N_2; the amide linkage (C_9–N_2) is rigid, but rotation is possible between C_9 and C_{10}.



I



II

The binding of an *N*-acetylmuramic acid residue to an active centre will depend primarily on ionic and hydrogen bonding. Examination of the two models showed that $O_{1'}$, N_1 and $O_{9'}$ of penicillin could occupy identical positions to $O_{7'}$, $O_{3'}$ and $O_{10'}$ in *N*-acetylmuramic acid. The antibiotic could therefore bind with part of an active centre normally binding an *N*-acetylmuramic acid residue, for the following reasons:

(1) All but one of the hydrogen bonding groups in penicillin are exposed on one face of the molecule (Fig. 1*b*), which closely resembles part of the face of the *N*-acetylmuramic acid molecule shown in Fig. 1*a*.

(2) The carboxyl groups in both molecules are in similar positions in the configurations shown in Fig. 1. They are both strongly acidic, with similar *p*K values (penicillin: *p*K 2·7 (ref. 9); *N*-acetylmuramic acid: *p*K 2·6 (ref. 7)), and therefore have the same ionic and hydrogen bonding possibilities at physiological *p*H values.

(3) The nitrogen atom N_1 in penicillin and the oxygen atom $O_{3'}$ in *N*-acetylmuramic acid occupy identical positions in the two models, and the nitrogen atom can form a hydrogen bond in a similar direction to one of the two that can be formed by the oxygen atom.

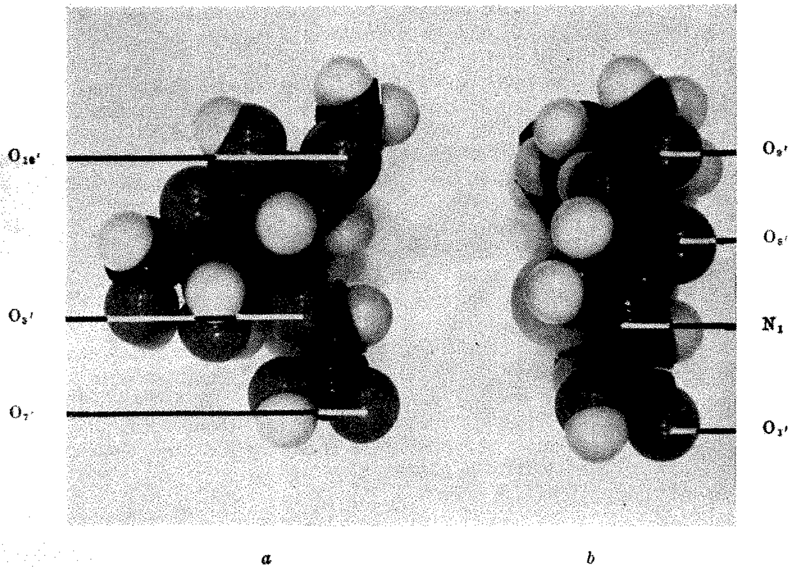


Fig. 1. Solid models of *N*-acetyl muramic acid (*a*) and benzyl penicillin (*b*) to show the similar distribution of reactive groups. *N*-acetyl muramic acid: $O_{3'}$, ether oxygen of the lactyl side-chain; $O_{7'}$, carboxyl group; $O_{10'}$, carbonyl oxygen of *N*-acetyl group. Penicillin: N_1, triply substituted nitrogen of β-lactam ring; $O_{1'}$, carboxyl group; $O_{9'}$, carbonyl of benzoyls ide-chain; $O_{8'}$, β-lactam carbonyl group

(4) The carbonyl groups $C_9O_9{}'$ in penicillin and $C_{10}O_{10}{}'$ in *N*-acetylmuramic acid arise in slightly different directions, but the two oxygen atoms occupy identical positions in the two molecules, and can each form a hydrogen bond in a common direction

(5) There are no large groups in penicillin which protrude beyond the face of the molecule shown in Fig 1*b* and which could interfere with binding of the antibiotic at the active centre The side-chain is curled back in the configuration illustrated (as found in the crystal[6]) and rotation about C_9–C_{10} cannot bring the phenyl ring near the reacting face of the molecule

Further evidence supports the hypothesis that these groups are involved in the binding of penicillin at a specific site Alterations in the structure of penicillin that do not affect the positions of these groups (for example, *N*-acyl derivatives of 6-aminopenicillanic acid) do not necessarily result in the loss of antibiotic activity[9,10] In contrast, loss of one of the reactive groups (for example, the carbonyl group $C_9O_9{}'$ as in 6-aminopenicillanic acid[11,12] and 6-picramidopenicillanic acid[13]) results in a several thousand-fold fall in antibiotic activity Changes which alter the relative positions of the binding groups (for example, in penicilloic acid[9], desthiopenicillin[9], the cyclic tripeptide derived from *N*-phenacetyl-L-cysteinyl-D-valine[14], compounds in which the β-lactam ring is replaced by a five- or six-membered ring[15] and penicillin hydroxamate[9]) result in total loss of activity

These considerations, if correct, give a rational basis for the action of penicillin at a molecular level The kinetics of penicillin action suggest that the compound has a very high affinity for the active centre[12] This could be achieved if the carbonyl group $C_8O_8{}'$ of penicillin (which has no counterpart in *N*-acetylmuramic acid) also binds to the active centre If penicillin binds through the groups that have been suggested, the $C_8O_8{}'$ carbonyl group will be favourably placed to interact with the site Since the carbonyl group is also the most reactive group in penicillin, it is possible that the molecule may first be bound to the active centre by ionic and hydrogen bonds described earlier, and then by reaction of $C_8O_8{}'$ with the active centre to form a covalent linkage that breaks down relatively slowly

It is not possible from a consideration of the structure of penicillin to identify the derivative of *N*-acetylmuramic acid involved in mucopeptide synthesis nor to decide the precise reaction inhibited by penicillin The *N*-acetylmuramic acid residue could be substituted at C_1 and C_6 without impairing the similarity of the molecule with penicillin Thus the sensitive reaction could involve a uridine nucleotide derivative of *N*-acetylmuramic acid undergoing a uridine transglycosidation at C_6, a reaction thought to be involved in mucopeptide synthesis[16–18]

The cephalosporins act in a similar way to penicillin[19] and contain the same binding groups in almost identical conformations[20] The same explanation could also account for their antibiotic activity

We thank many of our colleagues for help in the course of this work, Drs J Walker, Olga Kennard and J W Cornforth in particular Mr F Doré assisted in the construction of the wire models, and Miss P M Woodward made some of the calculations involved

DISTRIBUTION OF 5-BROMOURACIL AMONG THE PYRIMIDINE CLUSTERS OF THE DEOXYRIBONUCLEIC ACID OF *E. COLI*

By Dr RIVKA RUDNER, Prof HERMAN S. SHAPIRO and Prof ERWIN CHARGAFF

Cell Chemistry Laboratory, Department of Biochemistry, College of Physicians and Surgeons,
Columbia University, New York

SINCE the discovery of the biological specificity exhibited by certain microbial deoxyribonucleic acids[1], there has been much discussion of the function of these polymers as genetic determinants or as the carriers of biological information (cf refs 2 and 3) The possible importance, in this respect, of the specific sequence of the nucleotide constituents, and of its alteration as the cause of mutations, has been pointed out very early[4,5] Changes in the nucleotide pattern of a nucleic acid should, consequently, have far-reaching biological effects

The 6-ketopyrimidine 5-bromouracil is known to be accepted by certain bacterial cells as an analogue of thymine, being incorporated into the newly forming deoxyribonucleic acid in considerable quantities[6–8]. There are many biological consequences attending the incorporation of the halopyrimidine, an incorporation limited essentially to cells incapable of the synthesis of thymine[9] a gradual loss of viability[9] and, of particular interest, a very much increased rate of formation of mutants[10,11], sometimes with preferred sites of very high mutability[12]. At the same time,

Table 1. COMPOSITION OF DEOXYRIBONUCLEIC ACID OF TWO THYMINE AUXOTROPHS OF *E. coli* GROWN IN THE ABSENCE AND PRESENCE OF 5-BROMOURACIL

Mutant strain	Preparation No.	Growth supplements	Moles constituent per 100 moles total					Molar ratios			
			A	G	C	T	B	$A+T+B/G+C$	$A+C/G+T+B$	A/T or $A/T+B$	$B/T+B \times 100$

	2	$T+B$	24.4	25.6	25.7	10.6	13.7	0.95	1.00	1.00	56
I	3	T	24.6	25.5	25.6	24.3	—	0.96	1.01	1.01	—
	4	$T+B$	24.9	25.1	25.4	13.5	11.1	0.98	1.01	1.01	45

A, Adenine; *G*, guanine; *C*, cytosine; *T*, thymine; *B*, 5-bromouracil.

it is known that bacteriophage T_2 particles containing a high proportion of 5-bromouracil retain their infectivity[13] and that the transforming activity of nucleic acid preparations from *B. subtilis* is not annihilated by the incorporation of the analogue[14].

The interest of this laboratory in the problems relating to the arrangement of nucleotides in deoxyribonucleic acids[15] and the observation that the two normal 6-aminopyrimidine constituents, cytosine and 5-methylcytosine, apparently do not substitute for each other haphazardly within the nucleic acid chain[16] prompted two of us to investigate the effects of the intrusion of an abnormal analogue. The question to be answered was whether the living cell possesses a selection mechanism capable of distinguishing between the normal and the fraudulent 6-ketopyrimidine. A preliminary examination of one preparation of deoxyribonucleic acid of a thymine auxotroph of *E. coli*, strain I, led to the conclusion that the incorporation of 5-bromouracil gave rise to a severe distortion of the normal nucleotide pattern of the polymer[17]. The most remarkable observation was the high proportion of the halopyrimidine (nearly one-third of the analogue) that was found in the form of solitary units[18], that is, interjacent between purine nucleotides. This seemed to indicate a certain bias in the 'replacement' of thymine by 5-bromouracil. Further investigations have, however, furnished no evidence of gross non-randomness in the ability of the halopyrimidine to substitute for thymine within the polynucleotide chain.

The previous observations[17] are thus shown to be inconsistent with the weight of evidence, though we still lack an explanation of this anomaly. It should be emphasized that the original finding cannot have been due to the inadequacy of the hydrolysis procedure, which has in the meantime been shown to give nearly quantitative results[19]—and this is confirmed in the studies to be discussed presently—nor to an unusual lability of the glycosidic linkage of 5-bromodeoxyuridine. The rate of decomposition of this nucleoside has been found to follow first-order kinetics with a rate constant of 0.853 mole per cent per min. in 0.2 *M* sulphuric acid at 100°, a value not unduly different from those found for the other pyrimidine deoxyribonucleosides[20].

The present series of experiments started with an investigation of the mode of replication of a bacterial deoxyribonucleic acid in which the uptake of 5-bromouracil by another thymine-requiring mutant of *E. coli*, namely, 15 t^-arg$^-$, was followed. This auxotroph represents the 15 t^- strain[21] in which an additional requirement for arginine was produced with 2-aminopurine[22]. This strain offers the opportunity of achieving the synchronization[23] of the culture by depleting the cells of thymine during a starvation period of 30 min. and has the advantage of a readily controlled incorporation of 5-bromouracil. With 6 μgm./ml. of the halogenated analogue as the only supplement, the deoxyribonucleic acid produced in the first replication cycle contains nearly equal amounts of thymine and of the analogue (ref. 24 and unpublished observations). These studies revealed no gross alterations of the nucleotide sequence concomitant on the insertion of the halopyrimidine into the newly formed nucleic acid chain, as would have been predicted on the basis of the original findings[17]. A renewed investigation of the problem of 'replacement' seemed in order, with attention being paid this time not only to solitary pyrimidine units and a few of the coupled sequences but also to as complete a balance as could be established. The improvement in the separation methods achieved in the meantime[19] made this possible.

With the auxotroph t^-arg$^-$ grown in the presence of 10 μgm. of 5-bromouracil and 1 μgm. of thymine per ml. of synthetic medium[25] the contents in thymine and 5-bromouracil of the deoxyribonucleic acid were approximately equal after two cycles of replication (see Preparation 2 in Table 1). The same conditions, but with the omission of the halogenated pyrimidine were observed for the isolation of Preparation 1. The second mutant of *E. coli* examined here was strain I, which had been used previously[17]. It was grown, exactly as before (18 hr. at 37°) with the addition of 2 μgm./ml. of thymine, either alone (Preparation 3 in Table 1) or together with 10 μgm./ml. of 5-bromouracil (Preparation 4).

Deoxyribonucleic acid was isolated from the organisms by a procedure using a buffered phenol–water system at *p*H 9 (ref. 26). The bulk of contaminating ribonucleic acid was removed by precipitation with 10 per cent sodium chloride and the remainder by digestion with cryst. pancreatic ribonuclease. We reserve a complete account of all our experiments for a detailed publication to be submitted in due course, limiting ourselves here to a selection from the findings. The base composition of the preparations under comparison is shown in Table 1. In the preparation of nucleic acid from strain I investigated here the substitution of 5-bromouracil was more extensive (45 per cent of the sum of the 6-ketopyrimidines) than in the specimen studied previously (35 per cent)[17].

The hydrolysis of the preparations was performed as described in a previous publication[20] (2 per cent solution of nucleic acid in 0.1 *M* sulphuric acid, 100°, 35 min.). In all experiments but one, the pyrimidine nucleoside 3′,5′-diphosphates, indicative of sequences of the type purine–pyrimidine–purine, and the pyrimidine oligonucleotides carrying terminal phosphate groups at positions 3′ and 5′, respectively, indicative of pyrimidine clusters of varying length enclosed by purines, were separated by fractional chromatography on DEAE-cellulose[19]—a procedure permitting a much more complete accounting of all pyrimidine sequences released by acid hydrolysis than had been possible in the previous studies. Fig. 1 shows examples of the profiles of two separation experiments. It will be noticed that from the nucleic acid preparation produced in the absence of the halopyrimidine at least eight distinct fractions,

The nucleic acid preparations are numbered as in Table 1 The same abbreviations as in Table 1 are used, with *p* indicating the number of phosphate groups in the fragments having the general formula Py_np_{n+1} (Py = pyrimidine) No distinction is made between sequential isomers of the coupled units The figures are the averages of the results of two separate hydrolysis experiments, each chromatographic component being determined twice, the deviations from the averages are given in parentheses

going from solitary units to octanucleotide sequences, could be isolated, whereas with the preparation containing 5-bromouracil the longest runs separated clearly were those of five pyrimidine nucleotides in a row The significance of this difference, though observed often, cannot yet be appraised

The distribution of organic phosphorus among the fractions, summarized in Table 2, was essentially similar in preparations containing the bromopyrimidine and in those devoid of it In all chromatographic fractions, except Fraction I, the agreement between organic phosphorus (corrected for the fact that all nucleotide sequences carried an additional terminal 3′-phosphate) and pyrimidines recovered (see Tables 3 and 4) was satisfactory Only in Fraction I was the first figure higher than the second This points to the presence in this fraction of some non-nucleotidic organic phosphate arising, presumably, from the degradation of purine nucleotide units, this matter is being studied now

The hydrolysates of all preparations were, after separation into distinct size fractions (Fig. 1), studied further, as described in a previous publication[19] The results are shown in Table 3 with regard to the solitary and coupled pyrimidine units found in the preparations from strain 15 *t*-arg⁻, in Table 4, the same information, but extended to the pyrimidine triplets, is provided for strain I In the latter case, a second analytical procedure, more rapid and economical (1 mgm of nucleic acid being required instead of 20 mgm), but less adapted to specimens comprising three different pyrimidines, was applied to one hydrolysate In this method the hydrolysate is subjected directly to two-dimensional chromatography on filter paper in *iso*propanol-ammonia and in buffered *iso*butyrate[16] The Δε values used for quantitative spectroscopy have been given before[16], for 5-bromodeoxyuridine 3′,5′-diphosphate a $\Delta\varepsilon_{280-320}$ of 8,500 was used

The nucleic acid preparations are numbered as in Table 1, for abbreviations and manner of presentation see Tables 1 and 3 In analytical procedure I the separation of pyrimidine nucleotide units was carried out by means of a DEAE-cellulose column, as shown in Fig 1, in procedure II two-dimensional chromatography on filter paper was performed directly The value for B_3p_4 is an estimate based on the results of another experiment and has been excluded from the balances For other details, see Table 3

Tables 3 and 4 show that in all nucleotide sequences under comparison, and in both mutant strains examined, the relative contribution of 5-bromouracil to the sum of 6-ketopyrimidines equalled the relative

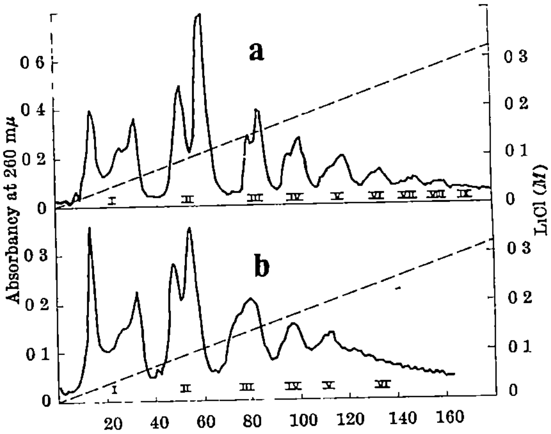

Fig 1 Chromatography of hydrolysates of deoxyribonucleic acid of *E coli*, mutant strain I *a*, grown in the absence, *b*, in the presence of 5-bromouracil Elution from DEAE-cellulose with an increasing linear gradient of lithium chloride in lithium acetate buffer (*p*H 5 0) and other techniques as in ref 19 Total volume of eluent 1,350 ml, 7-ml fractions

abundance of the analogue in the total nucleic acid Thus, in Preparation 2 the halopyrimidine accounted for 56 per cent of the sum of the 6-ketopyrimidines of the nucleic acid (Table 1) and the same figure was found for its relative frequency in the solitary and dinucleotide units (Table 3) The agreement was nearly as good in the preparation from strain I extending, in this case, even to the trinucleotides (Table 4) Moreover, the frequencies of thymine in the several units from Preparations 1 and 3 were quite similar to the frequencies of the sum of thymine and 5-bromouracil in the corresponding fractions from Preparations 2 and 4 While the final version of this article was being written, a note by Burton[27], dealing with another mutant strain of *E coli*, came to our attention, so far as comparison can be made, his findings are similar to those presented here

An observation pertaining to the structure of the normal nucleic acids produced without the interference of an analogue, deserves mention One gains the impression, also from previous observations[19,28], that there exists a certain bias in the disposition of thymine and cytosine, many nucleic acids appear to contain polythymidylic acid tracts that are much longer than those of polycytidylic acid This apparent trend is particularly noticeable in the case of the deoxyribonucleic acid of *E coli* which contains nearly equimolar quantities of thymine and cytosine One would have expected similar proportions of the stretches of varying length comprising only thymine or cytosine No units of the latter longer than C_3 have, however, been observed in hydrolysates of Preparation 1 (Table 1), whereas T_4 and T_5 units have invariably been noticed together with the various mixed fragments such as T_3C, T_2C_2, TC_3, T_4C, T_3C_2 and T_2C_3 The relatively greater abundance of cytosine among the small units, and the converse tendency of thymine, will be apparent even from the limited data in Tables 3 and 4

It must be understood, in conclusion, that the observation of an ostensibly random replacement of thymine by 5-bromouracil does not exclude the possibility that the analogue may exert certain non-random preferences for neighbours For example, we have no information about the relative frequencies of *pTpBp* and of *pBpTp* among the coupled units or about the frequency of adenine–thymine–adenine as compared with that of adenine–bromouracil–adenine among the solitary pyrimidine units Whatever may be the final explanation of the loss of viability and the occurrence of preferred locations of mutability, arising from the incorporation of 5-bromouracil, of which mention has been made before, it is clear that the substitution of the brominated analogue for thymine cannot be an inconsequential event

INACTIVATION OF EGG-WHITE LYSOZYME BY ULTRASONIC WAVES AND PROTECTIVE EFFECT OF AMINO-ACIDS

By DR F M DIETRICH*

University of Pittsburgh School of Medicine, Pittsburgh

DENATURING effects of ultrasonic waves on proteins have been demonstrated in many instances The subject has been reviewed by Grabar[1] and Griffin[2] In more recent studies, Kanig and Kunkel[3] reviewed the complex problem of ultrasonic effect on different proteins and discussed probable mechanisms involved in the denaturation processes Several enzymes are known to be inactivated by ultrasonic treatments, for example, blood catalase[4], salivary amylase[5], DNA-depolymerase[6], ribonuclease[7], pepsin, trypsin[8], milk reductase and peroxidase[9], succinic dehydrogenase[10], hyaluronidase[11], alkaline phosphatase[12], and diastase[13]

As shown in the following report, egg-white lysozyme is inactivated by ultrasonics and can be protected by several substances, including single amino-acids

Egg-white lysozyme, three times crystallized (Sigma Chemical Corporation) was used and activities were measured by a turbidimetric technique as described in another study[14] The standard concentration was 1 mgm /ml, dissolved in 0 6 *M* phosphate buffer (*p*H 6 2) The activity was shown to be linear

---

* Present address Scripps Clinic, Division of Experimental Pathology, 476 Prospect Street, La Jolla, California

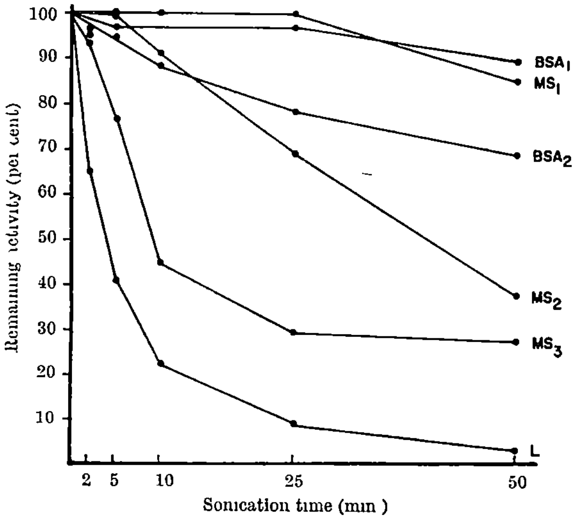

Fig 1 Sonication of lysozyme Protective effect of bovine serum albumin (BSA_1, 0 1 per cent BSA_2, 0 01 per cent) and 'Bentonite'-treated mouse serum (MS_1, 1 per cent , MS_2, 0 1 per cent , MS_3, 0 01 per cent) , *L*, lysozyme alone

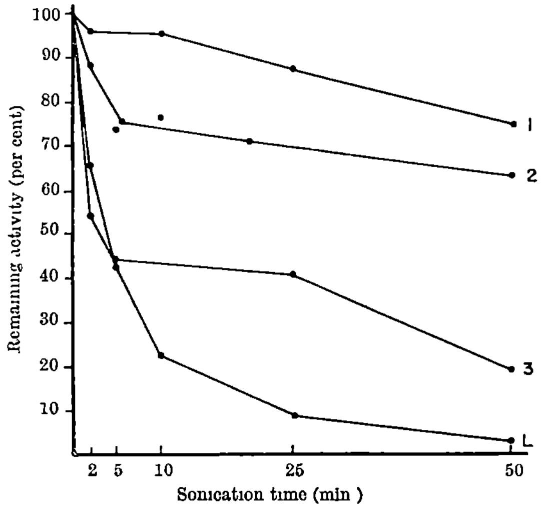

Fig 2 Sonication of lysozyme Protective effect of glycogen (1, 0 3 per cent, 2, 0 1 per cent, 3, 0 01 per cent, *L*, lysozyme alone)

during a 20-min incubation time and, in this assay, the activity was directly proportional to even higher enzyme concentrations (2 mgm /ml) Thus, enzyme activities determined under these experimental conditions can be regarded as initial rates Only in some experiments which were designed to determine the inactivation constant was the standard enzyme concentration changed When it was higher than 1 mgm /ml , the incubation time was reduced in order to get the true value for the initial rate In all inactivation and protection experiments, samples of 4-ml buffer, containing lysozyme (1 mgm /ml) and different amounts of L-amino-acids (only histidine was in the DL-form) or other substances were subjected to ultrasonic treatment for 2, 5, 10, 25 and 50 min Enzyme determinations were carried out in duplicate and the remaining activities reported as per cent of the original activity The values of the blank were subtracted from experimental values The *p*H of the amino-acid-buffer solutions was found to range from 5 8 to 6 3 However, in the experiments with DL-histidine (0 1 *M*) and arginine (0 1 *M*), the *p*H was 6 72 and 9 0 respectively Sonication was carried out by a 200-W , 10-kc /s oscillator (Raytheon, model *DF* 101) set at 1 25 amp The system was cooled with ice

Bovine serum albumin and mouse serum, previously treated with 'Bentonite' in order to absorb the lysozyme-like substance in the serum[14], showed a definite protective effect on lysozyme subjected to ultrasonic treatment (Fig 1) The protection depended on the concentration and was almost total with 0 1 per cent bovine serum albumin or 1 per cent mouse serum after 25 min sonication and fell slightly after 50 min In comparison, the activity of lysozyme solutions without bovine serum albumin or mouse serum was reduced after 25 and 50 min to approximately 8 and 3 per cent respectively

Glycogen also had a protective effect on lysozyme under the same experimental conditions (Fig 2) On the other hand, sodium chloride, magnesium sulphate, magnesium chloride and D-glucose tested in different concentrations had no protective effect Figs 3 and 4 summarize the data obtained with single amino-acids Several concentrations were

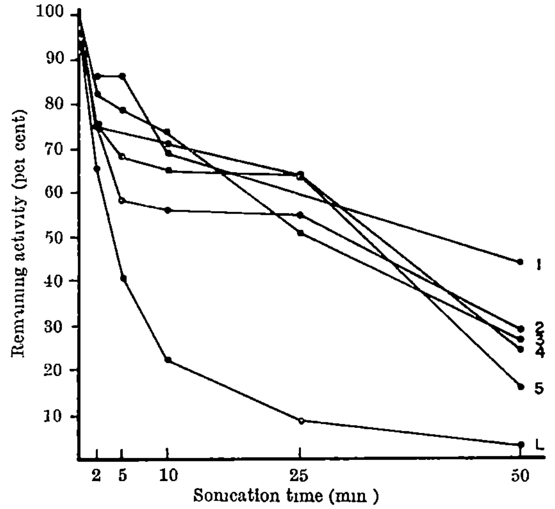

Fig 3 Sonication of lysozyme Protective effect of amino-acids and glutathione (1, glutathione, 0 01 *M* , 2, alanine, 1 *M* , 3, leucine, 0 01 *M* , 4, histidine, 0 1 *M* , 5, valine, 0 1 *M* , *L*, lysozyme alone)

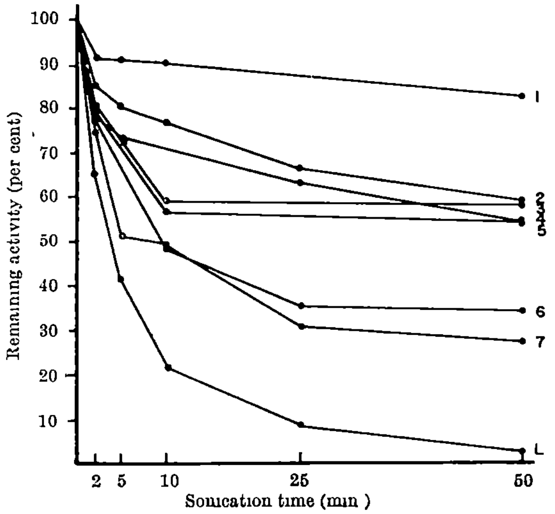

Fig 4. Sonication of lysozyme Protective effect of amino-acids (1, methionine, 0 08 *M* , 2, serine, 0 1 *M* , 3, arginine, 0 1 *M* , 4, asparagine, 0 1 *M* , 5, proline, 0 1 *M* , 6, glycine, 1 *M* , 7, lysine, 0 1 *M* , *L*, lysozyme alone)

tested Only the highest concentrations used in the experiments are presented Solubility, change in pH and inhibition of the enzyme activity were limiting factors in using higher concentrations Two different protection patterns were observed alanine (1 M), leucine (0 01 M), histidine (0 1 M) and valine (0 1 M) gave a high protection up to 25 min , but were less active thereafter (Fig 3) With lower concentrations, the activity at 50 min was often reduced to the level of the control, whereas at 25 min a protection effect was observed On the other hand (Fig 4), several amino-acids kept their protective effect for longer sonication periods and the remaining activity between 25 and 50 min was not significantly changed There was no correlation between molecular weight and protective effect Sulphur-containing substances, as methionine and glutathione, gave the best results

The ultrasonic inactivation of lysozyme did not show first order kinetics This behaviour was clearly demonstrated by several inactivation experiments using different enzyme concentrations In no instance did plotting of $\log \frac{A_0}{A}$ (where A_0 is the original activity and A the activity at time t) versus sonication time give a straight line By plotting $\log \frac{\mathrm{d}c}{\mathrm{d}t}$ versus $\log c_1$, the slope indicating the order (n) of the reaction ($\log \frac{\mathrm{d}c}{\mathrm{d}t} = \log k + n \log c$) was between 1 5 and 1 8 This finding was quite unexpected and indicates that ultrasonic inactivation of lysozyme follows more complicated kinetics Shugar[15] reported the ultra-violet-inactivation of lysozyme to conform to a first-order reaction

The enzyme assay, where ultra-violet-killed whole organisms (*M lysodeikticus*) are used as 'substrate' and the change in optical densities is measured spectrophotometrically, is not accurate enough to evaluate exact reaction constants

The mechanism of protection by single amino-acids, proteins and glycogen is now known Protecting agents may act by forming compounds with the enzyme active site, similar to an enzyme-substrate complex, or else they may act by protecting the entire molecule rather than peculiar areas Taking into consideration the molar ratio of enzyme to protective agents, it is more likely that another mechanism is involved Ultrasonic inactivation of enzymes and denaturation of proteins are often believed to be due to surface inactivation Protection may then occur by competition for available surface at the gas liquid interphases

ACID MUCOPOLYSACCHARIDES OF THE HUMAN UTERUS

By G LOEWI and R CONSDEN

Rheumatism Research Unit (Medical Research Council), Canadian Red Cross Memorial Hospital,
Taplow, Maidenhead, Berks

THIS article reports an analysis of the acid mucopolysaccharides of human uteri of several ages and conditions This was done in an effort to correlate any differences in such analyses with different conditions of the uterus The uterus was considered to be particularly suitable for such an investigation, since it undergoes marked alterations with age and pregnancy In addition, uterine collagen has been found to differ in its shrink temperature and fluorescence[1] from other adult human collagen, a difference which might be reflected in the associated mucopolysaccharide pattern Previous investigations of uterine acid mucopolysaccharides[2,3] have suggested the presence of hyaluronic acid and chondroitin sulphate, but these constituents were not isolated or individually characterized

Uteri were obtained at operation or at autopsy within a few hours of death The available material consisted of two uteri obtained respectively 2 and 4 days after parturition, and of a fibromyoma from a 38-year-old woman, normal pre-menopausal uteri were pooled from three women aged 36, 45 and 47 years, and post-menopausal uteri from six women aged 60–80 Uterus, including cervix, was freed from adhering tissue, secretions and loose tissue were, so far as possible, removed from the endometrium The tissues were then ground in a meat-mincer dehydrated in several changes of acetone and air-dried Fat was afterwards removed by washing with petroleum ether (b p 40°–60°) The minced, defatted material was digested with activated papain according to Scott's method[4] This was followed by the removal of nitrogenous contaminants and eventually by fractional precipitation of the calcium salts of polysaccharides by ethanol These methods and those used for analysis and identification of the mucopolysaccharides were as described by Meyer *et al* [5,6] Ethanol fractions were analysed for hexosamine (quantitative and qualitative[7]), uronic acid (orcinol and carbazole), nitrogen (micro-Kjeldahl) sulphate and acetyl (Laboratory Alfred Bernhardt Mulheim), specific rotation and susceptibility to testicular and bacterial hyaluronidase The 28 per cent ethanol fraction was subjected to further fractionation by the copper sulphate method of Cifonelli *et al* [8] Small amounts of hyaluronic acid were isolated from 36 per cent ethanol fractions by the cetyl pyridinium chloride method of Scott[4] 36 and 50

per cent ethanol fractions were analysed for keratosulphate by examination of hydrolysates for galactose by paper chromatography and by the anthrone reaction[9] Ethanol fractions (20–30 μgm each) were examined for acid polysaccharides by electrophoresis on cellulose acetate membranes (30 min at 15 V /cm in $M/40$ phosphate buffer, *p*H 7, stained with toluidine blue) Hydroxyproline was estimated in dried, defatted tissue after hydrolysis in 6 *N* hydrochloric acid for 16 hr by the method of Neuman and Logan[10]

Table 1 shows the types and quantities of acid mucopolysaccharide fractions obtained from the various groups of uteri The 18 per cent ethanol fraction and the precipitate obtained by treatment of the 28 per cent ethanol fraction by copper sulphate together constitute chondroitin sulphate *B*, which amount to about a half the acid polysaccharide isolated Its identity was confirmed by a low carbazole orcinol ratio (range 0 3–0 5) by liberation of galactosamine on hydrolysis, by negative rotation and by complete resistance to hyaluronidase The polysaccharide obtained from the supernatant part of the 28 per cent ethanol fraction after copper sulphate treatment accounted for about 10 per cent of the total material isolated from each batch of tissue The following properties suggested that it was heparitin sulphate positive rotation, liberation of glucosamine with only a trace of galactosamine on hydrolysis, sulphate, 4–8 per cent, acetyl, determined for one sample only, 4 2 per cent Carbazole orcinol ratio was relatively high (range 1 5 2 1), and the material was resistant to hyaluronidase Both the 36 and the 50 per cent ethanol fractions (sulphate, 6-12 per cent), consisted largely of chondroitin sulphate *A* and/or *C*, as evidenced by carbazole orcinol ratios of approximately 1 0, galactosamine as the predominating amino sugar, and digestibility by testicular hyaluronidase Slight degree of digestion by bacterial hyaluronidase and the presence of some glucosamine in the cases of the pre- and post-menopausal uteri suggested the presence of some hyaluronic acid This was confirmed by the isolation of a few milligrams of hyaluronic acid from each of these two groups by Scott's method[4] No evidence for the presence of keratosulphate was found in any of the 36 or 50 per cent ethanol fractions

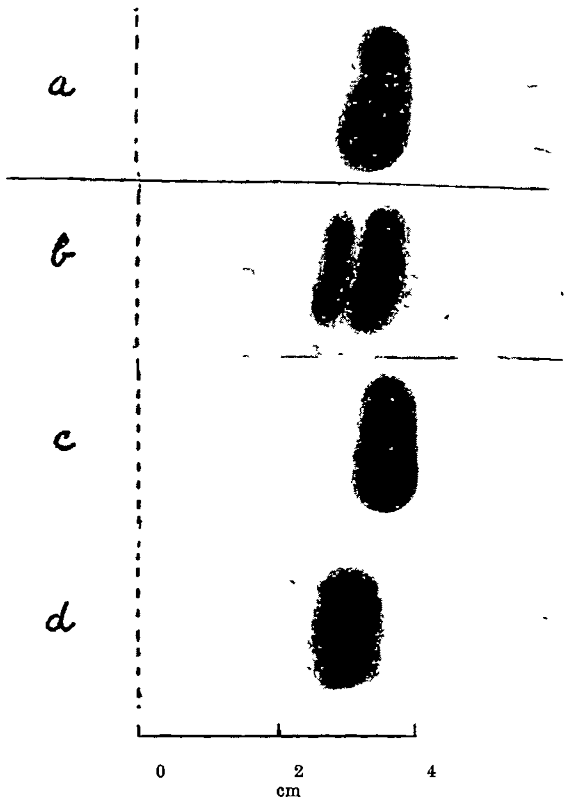

Fig 1. Electrophoretic pattern on cellulose acetate membranes *a*, 18 per cent ethanol fraction, *b*, 28 per cent ethanol fraction, *c*, precipitate from copper sulphate treatment of 28 per cent ethanol fraction, *d*, the copper sulphate supernatant Broken line represents position of origin

Fig 1 shows electrophoretic patterns given by (*a*) the 18 per cent ethanol fraction which was typical for chondroitin sulphate from a variety of sources, (*b*) the 28 per cent ethanol fraction, showing the presence of chondroitin sulphate together with the slower heparitin sulphate The copper sulphate treatment of this ethanol fraction resulted in almost complete separation of chondroitin sulphate which was precipitated (*c*) from heparitin sulphate, (*d*) which remained in the supernatant Electrophoresis of the 36 and the 50 per cent ethanol fractions showed that substantially only chondroitin sulphate was present, the former containing a trace of heparitin sulphate in addition

Meyer *et al* [5] found roughly equal proportions of chondroitin sulphate *B* and of *C*, with hyaluronic acid as a minor component, in adult connective tissue, such as pig heart valve and pig or calf tendon This pattern appears to be somewhat similar to that described here in uterine tissue, with, however, the interesting addition of heparitin sulphate Other collagen-rich tissues of human origin, such as skin[11], while containing amounts of total acid polysaccharides similar to those found in uterus, were relatively rich in hyaluronic acid, but no heparitin sulphate was found This polysaccharide was found in bovine lung and liver[12], in aorta[13] and in large amounts in the tissues from cases of Hurler's syndrome[14] This distribution does not suggest an association of heparitin sulphate with any particular tissue component

With the exception of a slightly higher proportion of chondroitin sulphate *B* in post-menopausal uteri, there are no marked differences in the distribution of individual acid polysaccharides in the four types of uterine tissue examined There were some differences in the yields of total acid polysaccharides extracted, but no clear correlation with age or type of uterus was apparent. Collagen content, as reflected by hydroxyproline–nitrogen values, was lower in post-partum than in other uteri. This difference was not, apparently, accompanied by differences in acid polysaccharide content.

We thank N. V. Organon of Oss, Holland, for a gift of bacterial hyaluronidase.

CONTROL OF ENDOGENOUS ADENOSINE TRIPHOSPHATASE ACTIVITY BY ENERGY-LINKED PYRIDINE NUCLEOTIDE REDUCTION IN MITOCHONDRIA

By Prof. BRITTON CHANCE and Dr. TAKERU ITO[*]

Johnson Research Foundation, University of Pennsylvania, Philadelphia

IN previous work[1] the existence of a pathway for the reduction of diphosphopyridine nucleotide (DPN) by succinate has been demonstrated and this pathway causes more DPN$^+$ reduction than any other substrate. In pigeon heart mitochondria, succinate-linked reduction of DPN$^+$ shows a specific requirement for adenosine triphosphate (ATP)[2,3] and the breakdown of the ATP expended in this reduction can be recorded as a change in *p*H by the use of a sensitive glass electrode technique[4]. Our results show that the oxidation-reduction state of DPN$^+$ exerts a powerful control over the endogenous ATPase of aerobic pigeon heart mitochondria; succinate-linked DPN$^+$ reduction inhibits endogenous ATPase of aerobic pigeon heart mitochondria by a very large factor. The measurement of ATP breakdown is sufficiently sensitive to detect amounts equivalent to carrier concentrations (~ 1 mμmole H^+/mgm. protein). The amount of ATP breakdown caused by succinate-linked DPN$^+$ reduction is measured and the stoichiometry of the reaction is evaluated.

The control of ATPase activity by the oxidation-reduction state of the respiratory carriers is one of the few links between this activity of the mitochondria and their property of oxidative phosphorylation. Investigations of ATPase activities in the presence of uncouplers such as dinitrophenol[5,6] also show inhibition by the oxidation-reduction state of the carrier[7-9]; 'complete reduction' appears to cause less than 70 per cent inhibition in liver mitochondria[8]. ATPase observed with no added activators is nearly 100 per cent inhibited by 'complete reduction'[9]. On the basis of these and related experiments, unique interpretations have been made regarding the role of respiratory carriers in oxidative phosphorylation[9], but other interpretations are being actively considered[8,10-12]. The basic question is whether the ATPase activity requires formation of a high energy intermediate with the oxidized or reduced forms of the respiratory carriers[10].

Here we observe the ATPase activity of mitochondria which contain both oxidized and reduced carriers; it is found that activity of endogenous ATPase is highly inhibited when energy-linked DPN has been reduced by succinate[1-3], but cytochromes remain partly oxidized. These results are consistent with the hypothesis that the reduced form of a respiratory carrier (DPNH) binds one of the intermediates of the energy transfer reactions of mitochondria[11,12]. The idea that the 'energy rich' form of the carrier involves the oxidized state[9] does not receive experimental support from these data.

These investigations shed some light on reaction mechanisms of reversed electron transfer, oxidative phosphorylation, and ATPase activity. The results illustrate a competition between 'hydrolysis' of an essential intermediate in ATPase activity (a 'dissipative' reaction) and the utilization of such an intermediate in reduction of DPN$^+$ (a 'conservative' reaction)[13-15].

The pigeon heart mitochondria were prepared as described previously[16] and were suspended in a magnesium-free medium containing 0.225 *M* mannitol, 0.075 *M* sucrose, and 0.003 *M* *tris*, at *p*H 7.4 (termed 'MST solution'). The temperature was 25°, protein was determined by the biuret method and ATP was determined optically. Determinations of hydrogen ion concentration were based on standard phthalate solutions.

The hydrolysis of ATP involves a formation of hydrogen ions which at *p*H 7.4 amount to 0.89 H^+/ATP (refs. 4 and 17). This change in *p*H was continuously recorded by a sensitive meter (Radiometer type 22) supplemented with an amplifier and chart recorder. Under the buffering conditions used, a change of hydrogen ion concentration of approximately 1 μ*M* (1.0 mμmoles) could be detected. Mitochondria were suspended in a continuously rotating cup in which the electrodes were immersed[4].

Inhibition of ATPase. The formation of hydrogen ions due to hydrolysis of ATP added to a suspension of pigeon heart mitochondria in the absence of added substrate is indicated in Fig. 1 (trace *A*) (the downward deflexion of the trace indicates formation of hydrogen ions); the addition of 85 μ*M* ATP is expended in an approximately first-order reaction in about 2½ min. The *p*H is reset to the initial value by two additions of sodium hydroxide, and a second addition of 85 μ*M* ATP reproduces the effects of the first addition.

---

[*] Present address: Ohio State University.

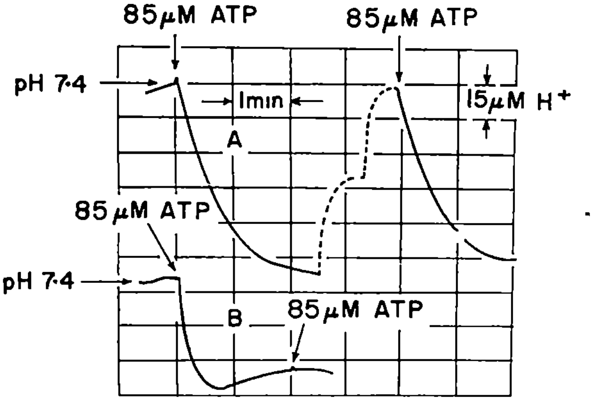

Fig 1 Hydrogen ion production from ATPase activity Trace *A*, endogenous ATPase activity of the pigeon heart mitochondrial suspension as measured continuously by a glass electrode The initial *p*H is 7 4, the arrows indicate the addition of 62 μM ATP, the downward deflexion of the trace indicates an increase of hydrogen ion concentration at a sensitivity of 15 μM H$^+$/large division 2 3 mgm /ml mitochondrial protein are suspended in MST medium at *p*H 7 4, 25° The dotted portions of the trace indicate the additions of sufficient sodium hydroxide to return the *p*H to the original level Trace *B*, hydrogen ion production from ATP breakdown in mitochondria supplemented with 0 6 m*M* succinate, initial *p*H 7 4 Other conditions identical to trace *A*

If the mitochondrial suspension is supplemented with 0 72 m*M* succinate prior to the addition of ATP, the formation of hydrogen ions is approximately twice as rapid (Fig 1, trace *B*) and the hydrogen ion production is much smaller Furthermore, a second addition of ATP under these conditions causes a scarcely measurable formation of hydrogen ions (the ratio of rates for the first and second additions of ATP exceeds 25)

The succinate concentration required to inhibit the breakdown of ATP according to the conditions of Fig 1*B* is about 400 μM These concentrations are of the same range as required for activation of succinate-linked DPN$^+$ (ref 18)

Effect of DPN-linked substrates Experiments with a variety of DPN-linked substrates show that the effect is highly specific for succinate, in the presence of malonate no inhibition is caused with malate, malate and glutamate, and α-ketoglutarate These substrates cause partial and not complete reduction of DPN$^+$ (ref 18)

Stoichiometric aspects A series of experiments have been carried out under the conditions of Fig 1*B* and in which the protein concentration was varied at constant concentrations of succinate and ATP A linear relation obtained so long as the added ATP was not expended The slope was 35 mμmole H$^+$/mgm protein for pigeon heart mitochondria 25°

Effects of inhibitors In agreement with spectrophotometric observations of inhibitors of the succinate-linked DPN reduction, similar effects were found for the ability of the succinate-linked pathway to inhibit endogenous ATPase (Fig 1*B*) The ATPase was reactivated by dinitrophenol, antimycin *A*, and hydroxyquinoline oxide (unpublished observations of Reiko Oshino) The effect of dinitrophenol is expected not only from its well-known ability to activate ATPase[5,6], but also from its inhibition of succinate-linked DPN reduction[1] The effects of antimycin *A* and hydroxyquinoline oxide are interpreted on the latter basis because they specifically interfere with DPN$^+$ reduction (see discussion later)

Reaction-rates The formation of hydrogen ions from ATP proceeds about twice as rapidly when DPN$^+$ is being reduced (Fig 1, trace *B*) (130 mμmoles/min /mgm protein) as when it is not (Fig 1, trace *A*) (40 mμmoles/min /mgm protein) The latter rate is in the range of values obtained with dinitrophenol at these concentrations of ATP

Correlation with DPN$^+$ reduction In order to demonstrate that DPN$^+$ reduction actually occurs under the conditions where the hydrogen ion formation is being observed, we illustrate in Fig 2 consecutive measurements of hydrogen ion formation (upper trace as recorded by the glass electrode) and DPN$^+$ reduction (lower trace recorded with the double beam spectrophotometer) 31 mμmoles H$^+$/mgm protein are produced as are 10 mμmoles DPNH/mgm protein

Steady-state hypothesis One explanation of the observed results is that sufficient ADP and phosphate are formed from the breakdown of the added ATP to allow rephosphorylation to occur On this basis the cessation of ATP breakdown represents a steady state rather than the end-point of the titration A number of considerations suggest that this is not the case

(1) The amounts of phosphate formed are well below the K_M value for oxidative phosphorylation[16,19] If a steady state exists, it should respond to further additions of ATP with a measurable hydrogen ion production at approximately the same initial rate as the first addition (Fig 1, trace *B*)

(2) The addition of phosphate to mitochondria which have been treated as indicated by Fig 1*B* allows an assay of ADP remaining in amounts which roughly account for the breakdown of ATP (refs 16 and 20)

(3) Addition of ATP in the absence of magnesium ions can lead to an inhibition of respiration and leads to conditions favourable to the accumulation of low concentrations of ADP and inorganic phosphate[21]

(+)DPN-linked substrates causing the reduction of only part of the DPN, but nevertheless activating respiration, do not inhibit the endogenous ATPase

These and other considerations lead us to set aside the 'steady-state' hypothesis in favour of the one outlined here

Competitive inhibition of endogenous ATPase by energy-linked DPN$^+$ reduction It is proposed to explain two characteristics of Fig 1 (1) That the formation of hydrogen ions, attributed to breakdown of ATP, is accelerated by the concomitant reduction of DPN$^+$ (2) That further breakdown of ATP after the completion of DPN reduction is severely inhibited

These results lead us to consider a competitive reaction between the hydrolysis of an intermediate in ATPase action and the utilization of such intermediates in DPN$^+$ reduction

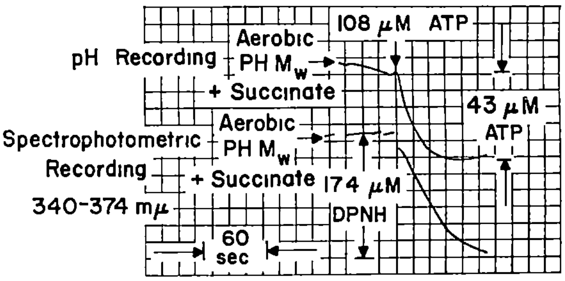

Fig 2 Consecutive glass electrode recordings of increases of hydrogen ion concentration following addition of ATP to succinate-treated mitochondria (1 4 mgm /ml pigeon heart mitochondria) (top trace) and spectrophotometric recordings of DPN reduction (1 7 mgm /ml pigeon heart mitochondria) (bottom trace) The calibration of the glass electrode trace was made by the addition of known concentrations of sodium hydroxide The calibrations of the spectrophotometric trace were based on the extinction coefficient of DPNH of 2 3 mM^{-1} × 0 5 cm^{-1} at wave-lengths of 340–374 mμ (212–4)

Equations representing the competitive inhibition of endogenous ATPase activity follow

$$\text{ATP} + X \rightleftharpoons X \sim \text{P} + \text{ADP} \quad (1)$$

$$X \sim \text{P} + \text{I} \rightleftharpoons X \sim \text{I} + P_i \quad (2)$$

$$X \sim \text{I} + \text{DPN}^+ + \text{succinate} \rightleftharpoons \text{fumarate} + \text{DPNH} + \text{H}^+ + X + \text{I} \quad (3)$$

$$X \sim \text{I} + \text{DPNH} \rightleftharpoons \text{DPNH} \sim \text{I} + X \quad (4)$$

$$X \sim \text{I} \overset{\text{HOH}}{\rightleftharpoons} X + \text{I} \quad (5)$$

This mechanism is formulated in terms of a present view on the mechanism of oxidative phosphorylation[12], but this does not exclude its interpretation in terms of other mechanisms in so far as they can be shown to be consistent with the experimental observations The equations embrace the following ideas

(1) A spontaneous 'hydrolysis' of labile intermediates formed from ATP (equation 5)

(2) A competition for the labile intermediate between 'hydrolysis' and an energy-linked reaction (equations 3 and 4) (Competition between 'dissipative' and 'conservative' pathways[13–15])

(3) Succinate-linked DPN+ reduction is already identified as an energy-requiring reaction and is the most likely one to be involved[1–3], but other carriers can also be affected by this reaction.

(4) The carriers involved in the reaction, particularly DPN+, have the property of binding and thereby expending an intermediate essential to the ATPase activity (equation 4)

The inhibitor sensitivity is consistent with equations (3) and (4), substances which block electron transfer from succinate (malonate, antimycin *A*, hydroxyquinoline oxide)[22] block effects on the ATPase activity In connexion with the effects of antimycin *A* and hydroxyquinoline oxide, we prefer the simple hypothesis that they react by inhibiting electron transfer and thereby prevent the flow of electrons from succinate to DPNH The hypothesis that they activate ATPase[23,24] now appears to be consistent with experimental observations, they activate ATPase by inhibiting equations (3) and (4) The possibility that they activate equation 5 is not eliminated, but does not affect the conclusions drawn here

Lack of appreciable inhibition of the endogenous ATPase activity in the presence of malate, glutamate (and malonate) is in accordance with the observation that these substances reduce only a fraction of the DPN+ reduced by succinate and ATP (ref 1) Thus the concentration of reduced DPN+ may be stoichiometrically insufficient to allow reaction (4) to go to completion and consequently reaction (5) may proceed

Evidence that DPNH is involved in an especial binding in mitochondria is afforded by the greatly enhanced fluorescence of the coenzyme under these conditions[25] Recent data obtained by R W Estabrook of this laboratory and elsewhere[26] suggest that the enhancement factor considerably exceeds that of a binary complex[27] and more closely approaches that of a ternary complex[28] Further evidence also suggests that a protein component may be involved in this binding in view of the ultra-violet peak in the activation spectrum[26]. Thus the experimental evidence speaks in favour of a ternary compound of pyridine nucleotide, a protein component and a third component which, on the basis of these data, is essential to endogenous ATPase activity

A highly active endogenous ATPase (about 25 per cent of the DPN-stimulated value) is characteristic of heart mitochondria, but is not noted in rat liver and kidney mitochondria As an explanation of this basic difference of the two types of preparation we offer the possibility that the stoichiometric ratios of the ATPase intermediate of equations (1–5) relative to that of DPNH and of other carriers which may be involved in the binding varies in the different preparations; in rat liver mitochondria the amount of the ATPase intermediate is sufficiently small that it is stoichiometrically expended by a small extent of reduction of DPN (and other carriers) In the pigeon heart mitochondria it is apparent that the stoichiometric requirements for ATPase inhibition are only met by the high degree of DPN reduction achieved by the energy-linked pathway

Obviously, other factors enter into the control of endogenous ATPase activity, that is, under the conditions used in the measurement of oxidative phosphorylation excess phosphate is present and inhibits equation (2) from proceeding from left to right

Superficially the inhibition of the endogenous ATPase by DPN+ reduction resembles the inhibition of dinitrophenol-stimulated ATPase by anaerobiosis[8] Here, too, the possibility of DPN reduction was considered as an inhibitory factor However, the quantitative nature of the inhibitory effects vastly differ, more than 96 per cent inhibition of the endogenous ATPase is obtained in the aerobic succinate-treated mitochondria In the dinitrophenol-treated mitochondria only about 50 per cent inhibition can be obtained by anaerobiosis and this may be because only a portion of the DPN can be reduced under these conditions[29] Thus mechanisms of the forms of equations (1–5) may be applicable to other systems according to the extent to which DPN+ and other carriers can be reduced in the presence of the uncoupling agents used to activate ATPase

The stoichiometric aspects of the results of these data are of considerable interest in determining the efficiency with which equations (3) and (4) compete with equation (5) under the conditions of our experiment, and furthermore are of value in determining the stoichiometry with which ATP participates in equation (6)

$$n\,\text{ATP} + \text{succinate} + \text{DPN}^+ \rightleftharpoons n\,\text{ADP} + n\,P_i + \text{fumarate} + \text{DPN}^+ + \text{H}^+ \quad (6)$$

However, before the stoichiometry can be determined accurately, the contribution to the *p*H change caused by reduction of intramitochondrial DPN+ must be determined In order to record this change in *p*H, we utilize the fact that addition of glutamate to the succinate-treated mitochondria leads to DPN+ reduction without the need for external energy sources[1] (the reaction under these conditions is oligomycin-insensitive[30]) A determination of the hydrogen ion production caused by glutamate-activated reduction of pyridine nucleotide gives a value of 6 5 mμmoles H+/mgm protein Thus the value for hydrogen ion formation from succinate and ATP (35 mμmoles/mgm protein) can be revised downwards to 28 mμmoles/mgm protein The value from Fig 2 is revised downwards to 24 mμmoles/mgm protein Investigations reported elsewhere[4] indicate that 0 89 H+ is released per mole of ATP broken down at *p*H 7 4 and 25° Using this conversion factor, we obtain for the two determinations mentioned in this article 31 and 27 mμmoles ATP/mgm protein

Since the average value for DPN$^+$ reduction by succinate and ATP in pigeon heart mitochondria is 10 mμmoles/mgm protein (the particular value in Fig 2 is identical to this) the stoichiometric ratio of equation (6) is between 2 7 and 3 1 ATP/DPNH Values determined in this manner are likely to be maximum values for two reasons (1) The effectiveness of the competition with the 'hydrolysis' reaction (equation 5) is not surely known, although the rates are in favour of equations (3) and (4) (2) Carriers other than pyridine nucleotide, although present in smaller concentrations than DPNH, are concomitantly reduced The stoichiometric coefficient obtained by this procedure lies within the range of values determined by other methods[31] although it is significantly larger than the lowest values obtained by spectrophotometric observations of ADP formation[31]

Control of metabolism The results of these experiments are of some interest with respect to present-day theories of metabolic control Theories which propose control of respiration by control of the level of substrate in the mitochondria would seem in the light of these experiments to lead to an activation of endogenous ATPase, a wasteful process Control of metabolism by ADP or phosphate in the presence of excess substrate seems to be more efficient and is, in fact, the type of control that is observed in excised muscles and ascites tumour cells suspensions[32]

GLUCOSE METABOLISM IN A LOW-GLYCOLYSING TUMOUR, THE MORRIS HEPATOMA 5123

By YU CHEN LIN, J. CLINT ELWOOD*, ADOLFO ROSADO†, HAROLD P. MORRIS and SIDNEY WEINHOUSE

Institute for Cancer Research, and Chemistry Department, Temple University, Philadelphia, and the National Cancer Institute, Bethesda

CONSIDERABLE attention has been focused recently on a new carcinogen-induced, transplantable rat hepatoma, the Morris hepatoma 5123 (ref 1), because it differs markedly from all other transplantable rat liver tumours so far studied in retaining, to a greater extent than has hitherto been observed, many of the morphological and metabolic characteristics of the normal hepatic cell Various properties of this tumour have been described in the recent literature[2–10], and a summary of its enzymatic characteristics may be found in a recent review[11]

Probably the most striking characteristic of this tumour is a very low glycolytic rate Slices of this tumour apparently do not follow the rules of usual behaviour of malignant neoplastic cells in that they produce very small quantities of lactate in the presence of glucose (refs 4 and 10 and unpublished observations of Woods, M , and Burk, D) Although not measured in earlier generations, presumably this characteristic has been retained through 25 serial transfers during the past five years In a study of the glucose metabolism of whole homogenates of these tumours, we have confirmed the low glycolytic rate and we have found that this property is due at least in part to a low glucokinase activity

The tumours used in this work were twenty-third and twenty-fifth generation transplants of sub-lines *C* and *D*, made by subcutaneous, intramuscular or intraperitoneal trocar injection of minced tumour tissue in female rats of the Buffalo strain Approximately 60–80 days after implantation, when the tumours reached a size of 1–2 cm diameter, the rats were decapitated and the tumours carefully but rapidly dissected from surrounding tissue and central necrotic material, if any The tissue was weighed, minced with sharp-pointed scissors, and homogenized Using a Potter–Elvehjem homogenizer with a plastic pestle, the tissue, diluted with twice its volume of distilled water, was dispersed by means of five or six passes of the pestle while cooling in ice Pieces of tissue debris were removed by filtration through glass wool and a portion of the homogenate was taken for dry weight determination

---

Glucose, uniformly labelled with carbon-14 (glucose-U-^{14}C), was obtained from the Volk Radiochemical Co, Chicago Glucose-6-phosphate and the hexokinase, type V, were obtained from the Sigma Chemical Co

Each Warburg vessel contained 0 5 ml of the tissue suspension, containing 30–35 mgm dry weight in 2 1 ml total volume of medium with the following final composition phosphate buffer, *p*H 7 4, 0 02 *M*, Mg^{++}, 0 002 *M*, potassium chloride, 0 08 *M*, adenosine triphosphate, 0 002 *M*, cytochrome *c*, 1 mgm per vessel, and diphosphopyridine nucleotide, 2 5 mgm per vessel Where added, glucose and glucose-6-P were in a final concentration of 0 005 *M* Incubations were carried out with shaking for 1 hr at 37° with air in the gas phase, and a folded filter paper strip soaked in potassium hydroxide in the centre well The reaction was terminated by tipping in 0 2 ml of 20 per cent trichloroacetic acid from the side-arm, and after 15 min additional shaking, carbon dioxide was recovered from the centre well for radioactivity assay[12] and lactate was determined according to Barker and Summerson[13]

The pertinent results concerning respiration and aerobic glycolysis are summarized in Tables 1 and 2 The endogenous respiration of the fortified whole homogenate of 5123 was very high, corresponding to a Q_{O_2} of 16 The addition of glucose to the homogenate lowered oxygen uptake slightly and the lactate production was quite low, corresponding to a $Q_L^{O_2}$ of only 0 3 Measurement of the radioactivity of the respiratory carbon dioxide revealed that only a very small quantity of glucose was oxidized, accounting for only 8 per cent of the total respiration In the presence of succinate, glucose again lowered respiration somewhat, and both lactate production and glucose oxidation were very low However, addition of yeast hexokinase brought about a remarkable stimulation of glycolysis Under these conditions the aerobic formation of 18 6 μmoles lactate corresponds to a $Q_L^{O_2}$ of 12, a value as high as those displayed by slices of both primary and transplanted hepatomas[14–16] At the same time there was also a three- to five-fold stimulation in the oxidation of glucose carbon to carbon dioxide, raising the proportion of total respiration accountable by glucose oxidation to 38 per cent

Recently another hepatoma, number 7800, was induced in a male rat by the same procedure used for induction of the 5123 tumour in a female rat[1], and has been transplanted into the third generation (The details concerning the induction of hepatoma 7800 and other slowly growing transplantable rat hepatomas will be described in another publication from the National Cancer Institute) The experiment in Table 1 shows that a homogenate of this tumour also displays the same low glycolytic activity, and responsiveness to hexokinase

For comparison, similar data are presented for the Dunning hepatoma *LC*–18, for a primary rat tumour induced by feeding a diet containing 0 06 per cent of dimethylaminoazobenzene, and for a transplantable mouse neoplasm, sarcoma 37, in the ascites form Homogenates of the Dunning and the *DAB* tumours had a lower respiration than the 5123 tumour, and displayed a moderate glycolysis which was enhanced by addition of hexokinase, though the effect was not so marked as that observed with the 5123 and 7800 tumours Glucose oxidation in these particular tumours was very low and responded markedly to hexokinase In contrast, the homogenate of sarcoma 37 had a high respiration and a high glycolysis in the presence of glucose Neither was further stimulated by hexokinase, and glucose oxidation, though low, was also not affected by this enzyme These results leave no doubt that under the conditions of our experiments the 5123 tumour had a low capability for lactate production and glucose oxidation, and that these defects can be repaired by the addition of hexokinase These results also indicate that glucokinase limits glycolysis as well as glucose oxidation in variable degree in other hepatomas

Further evidence for hexokinase as the limiting step in glucose utilization by the 5123, the 7800 and the Dunning *LC*-18 tumours is shown in Table 2 With these tumours lactate production was much higher from glucose-6-P than from glucose, being of the order of that obtained with glucose and hexokinase With sarcoma 37, however, under a variety of conditions, lactate formation was no greater with glucose-6-P than with glucose as substrate

The low glucokinase activity of these tumours may be regarded as yet another characteristic in which they resemble liver Low glucokinase activity has been recognized for many years as a characteristic property of liver[17], and recent studies[18] have also shown that the rat liver enzyme differs markedly from hitherto-described hexokinases of other tissues in having an apparently very low affinity for glucose, so that high concentrations are required for maximal activity Glucokinase assays in the Morris 5123 and 7800 tumours carried out recently in our laboratory, using a sensitive spectrophotometric assay procedure based on triphosphopyridine nucleotide reduction in the presence of excess glucose-6-P dehydrogenase, are in accord with these metabolic studies in displaying a glucokinase activity so much lower than that of normal rat liver that assay values have been at the limit of measurement[19] Whether this is due to a deficiency of enzyme, or to some as yet undetermined inhibitor effect, such as has been proposed by Woods and Hunter[20] for the *S*91 melanoma, remains for further investigation

In contrast with the vast majority of tumours, including both primary and transplantable liver neoplasms, the Morris hepatomas 5123 and 7800 can grow (albeit slowly) and kill their hosts with apparently only minimal use of glucose as a source of glycolytic or respiratory energy A more detailed investigation of the glucose (and fatty acid) metabolism as well as a study of the properties of the hexokinase of these and other liver tumours is now in progress

SEPARATION OF STRONTIUM FROM MILK AND PROTEIN SOLUTIONS BY GEL FILTRATION

By W H S. GEORGE*

Department of Experimental Pathology, University of Birmingham

GEL filtration[1] has provided a simple and rapid method for the fractionation of water-soluble substances The process depends on differences in molecular size and the gel can be regenerated after each cycle

Gel filtration on 'Sephadex' (Pharmacia, Uppsala, Sweden) has been used in investigation of the complexes formed between heavy metals and small molecules or ions[2] It was found that heavy metals could be bound to the 'Sephadex' under certain conditions Radioisotope investigations[3] of submicrogramme quantities of inorganic ions have shown that the ions enter the gel phase and can be separated quantitatively from proteins

The factors[4] known to influence the removal of salts from particular proteins, by gel fitration, are flow-rate, particle size of the bed material, volume and viscosity of the sample Although strontium has been separated from milk for analytical purposes by ion exchange[5], it seemed possible that a similar separation might take place by gel filtration

Columns of 'Sephadex *G* 25' and '*G* 50' were prepared by washing the 'Sephadex' three times with 5–10 times its volume of phosphate-buffered saline, 0 5 *M*, *p*H 7 4 Each time the gel was allowed to settle and the fine particles decanted off The gel was then slurried into a vertical burette, the lower end of which was plugged with glass wool and the column allowed to settle Columns were prepared varying in length between 24 and 32 cm and were 0 6 cm diameter Each column was washed through with 100–200 ml of phosphate saline buffer until the eluates showed a similar electrical conductivity, demonstrating that the gel was thoroughly saturated with the eluant.

10 ml of milk were centrifuged at 3,000 r p m for 5 min in a bench centrifuge at room temperature and the fat skimmed off 4 ml of the skimmed milk were thoroughly mixed with 1 ml of strontium chloride containing 0 6 mgm of strontium per ml The 5 ml of milk/strontium mixture were applied to the top of the column, and after they had soaked into the gel were eluted with phosphate saline buffer The eluate was collected in 3-ml aliquots by a mechanical fraction collector At the end of the elution period (120 ml) the column was extruded from the burette and divided into three parts, each part being suspended in phosphate saline buffer

The aliquots of the eluate collected during the equilibration period with buffer, and after addition of the milk/strontium mixture were suitably diluted and their optical density measured at 280 mμ for protein The presence of fat in the eluates was detected by dropwise addition of a sample from each aliquot on to filter paper which, when dried, was stained with a fat stain, sudan black The spot test indicator, *p*-dimethyl amino-benzylidene rhodanine in saturated alcoholic solution, gives a rose pink coloration with strontium The skimmed milk before and after addition of strontium, each aliquot of eluate and the three parts of the column, together with the original 'Sephadex', were all tested for the presence of strontium

A sample of whole milk was also contaminated with a detectable amount of strontium chloride, and after centrifugation the fat and skimmed milk tested for the presence of strontium

---

* Present address Pathology Department, Derbyshire Royal Infirmary, Derby

Similar elutions of 1 per cent human γ-globulin in saline, strontium chloride solution and mixtures of both were carried out with phosphate saline buffer from 'Sephadex' columns

Optical density measurements on the eluates from the milk/strontium mixtures revealed those eluates in which protein could be detected and the peak concentration coincided with the eluates containing the maximum amount of fat (Fig 1) The electrical conductivity of the eluates remained unaltered, indicating an absence of any excess ion in them By comparison, the eluates (Fig 2) from γ-globulin strontium mixtures showed a peak conductivity corresponding to the presence of strontium as shown by spot testing

The skimmed milk gave a negative reaction for the presence of strontium before its addition and a positive reaction afterwards All the eluates were negative, but strontium could be detected in the washings from the upper third of the extruded column and also adherent to the gel particles which changed colour on the addition of *p*-di-methyl amino-benzylidene rhodanine 'Sephadex alone showed no reaction with this reagent When strontium was added to whole milk and then centrifuged it could only be detected in the skimmed milk and not in the fat

Although certain metals give colour reactions with *p*-di-methyl amino-benzylidene rhodanine, calcium, sodium and potassium are inert and the milk prior to the addition of strontium was negative This reagent therefore would appear suitable for testing for the presence of strontium and is quicker and easier than group analysis or flame photometry, particularly in the presence of sodium

Unskimmed milk has a viscosity too high for it to be eluted from the columns, and so it was necessary to skim the milk prior to elution from a column Phosphate saline buffer was used to avoid precipitation of protein on the column by variation in *p*H or ionic strength

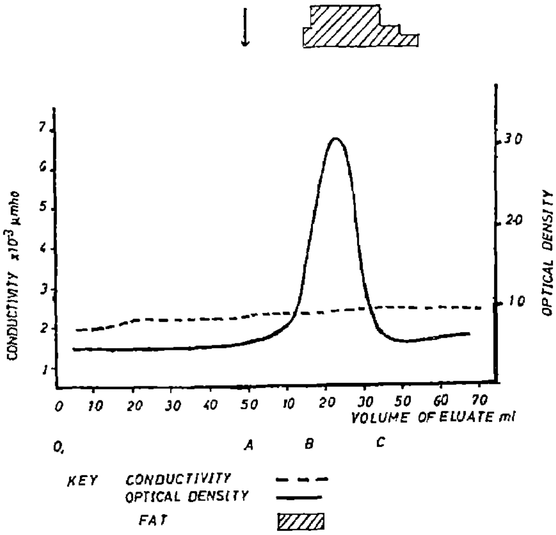

Fig 1 The elution diagram for a sample of skimmed milk to which strontium had been added The column 28 cm long × 0 6 cm diameter was of 'Sephadex *G* 50', and the eluant phosphate saline buffer The optical density of the eluates has been measured at 280 mμ for proteins and the conductivities in μmho The eluates from 0 to *A* were collected during the period of equilibration with the eluant and show constant conductivity and optical density At the point *A*, marked with an arrow, 5 ml of milk/strontium mixture were added At the point *B* to *C* the rise in optical density demonstrates the presence of protein while the shaded area demonstrates the eluates containing fat Despite continued elution, no eluates demonstrate the presence of strontium when tested with the spot test indicator, but the upper third of the 'Sephadex' column when extruded contained strontium This demonstrates the complete separation of strontium from skimmed milk

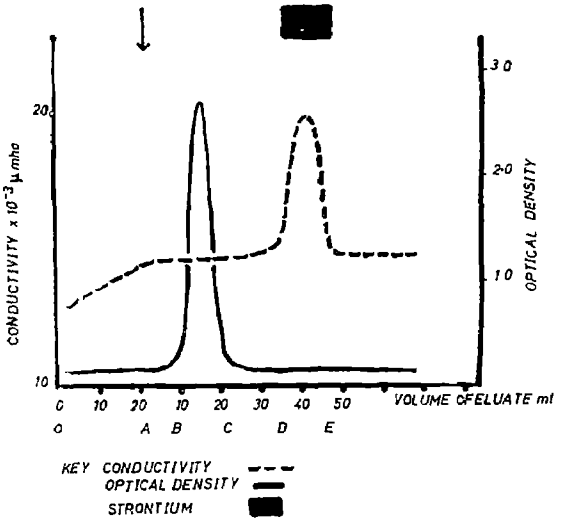

Fig 2 The elution diagram for a solution of human γ-globulin in phosphate saline to which strontium has been added to a concentration of 0 12 mgm /ml of strontium The column of 'Sephadex *G* 25' was 30 cm long × 0 6 cm diameter, and the eluant phosphate buffer *p*H 7 4 The period 0 to *A* represents the period of equilibration of the column with phosphate saline when equilibrium conductivity and optical density were attained At point *A* 9 ml of γ-globulin strontium solution were added to the column and eluted The period *B* to *C* represents the eluates containing protein as demonstrated by the optical density *C* to *D* represents the volume of eluant separating the eluates containing protein from those containing strontium This volume was equivalent to 1 column volume *D* to *E* represents the eluates containing strontium, reacting positively with the spot test and demonstrating the rise in conductivity Absence of positive spot test and equilibrium conductivity over eluates *B* to *C* demonstrate absence of strontium in these eluates

Since no strontium was detected in the eluates after elution of the milk/strontium mixtures, but was found on the upper third of the column, it would appear that gel filtration is a suitable procedure for the removal of strontium from milk However, the sensitivity of the spot test may not be sufficiently great to detect very small quantities of strontium passing into the eluates Radioisotope investigations are necessary to clarify this point since they are more sensitive The apparently complete removal of artificially added strontium in a concentration of 0 12 mgm /ml from milk is not strictly comparable to the removal of strontium which has been added to milk during its secretion by the cow, since in the latter case the amount is smaller and may be more difficult to remove

No assessment of the amount of protein-bound strontium was made, but this is likely to be low when the milk contains an excess of ionized and bound calcium If the protein-bound strontium, when present in cows' milk, is in equilibrium with ionic strontium, then removal of the ionic strontium on the column should successively displace the strontium from its protein conjugate, particularly in the presence of excess calcium It would be possible to wash the columns with calcium salts to ensure saturation prior to elution of the milk and thus aid removal of strontium

The observation that strontium is not associated with the fat after skimming but remains in the skimmed milk implies that all the strontium present in milk is potentially available for absorption on a 'Sephadex' column Had any strontium been associated with the fatty fraction skimmed off the milk it would be unavailable for absorption by a column since the fat was too viscous to traverse a column as we prepared it.

The importance of this method of removal of strontium from milk lies in the ease of handling small samples of milk to which strontium has been added and the speed with which all the strontium detectable chemically can be removed from the milk. Radiostrontium absorbed on to such a column would be readily estimated after ashing the column.

The use of this method for removing strontium and possibly similar ions from protein mixtures is demonstrated by Fig. 2, in which there was a column volume difference in the eluates between the protein and the strontium, sufficient to yield clean separation. The observation that strontium came off the column in the case of γ-globulin/strontium mixture but remained associated with the column when milk/strontium mixture was eluted may be explained by differences in the composition of the samples. The γ-globulin/strontium chloride mixtures and the milk/strontium mixtures were all eluted by phosphate saline buffer but the presence of other ions, carbohydrate and fat in milk may have caused binding of the strontium to the gel bed.

The possible benefits of gel filtration over ion exchange procedures in the analysis of the strontium present in milk are that gel filtration appears to need only one column procedure and ion exchange requires at least two. The strontium is retained on a column which is readily ashed in preparation for counting procedures in the case of gel filtration, and no preliminary separation of proteins is required.

Quantitative radioisotope investigations comparing the ion exchange and gel filtration procedures need to be carried out.

The largest volume of milk put through a column has been 5 ml., which required about 1 hr. of elution time; the factors involved in using larger volumes and the potability of the product have not been investigated.

I thank Messrs. Pharmacia, Uppsala, Sweden, for gifts of 'Sephadex', and the Endowment Fund of the United Birmingham Hospitals for a grant.

FRACTURE REPAIR AFTER TREATMENT WITH DEOXYRIBONUCLEIC ACID FROM FISH

By Dr. E. A. TONNA and Dr. E. P. CRONKITE
Medical Research Center, Brookhaven National Laboratory, Upton, New York
AND
Dr. F. J. SANEN
Fougera and Co., Inc., Hicksville, New York

THIS investigation was stimulated by reports of Jacob[1] and Fauchet[2] claiming that marked differences were noted in resorption of the fracture clot, the osseous transformation of the cartilaginous masses, and the spreading of the hæmatopoietic tissue in the intertrabecular spaces of the new-formed bone in human and rat, in comparison with their controls, when deoxyribonucleic acid (DNA) from fish was administered. Meek and Hewer[3] reported the occurrence of duodenal adenocarcinoma in mice following treatment with fish milt-DNA. This was also reported in tropical fish (Cichlids) by Stolk[4].

In view of the importance of enhanced fracture repair in aged individuals and in cases with difficulties in bone healing, it was felt necessary to repeat the histological experiments of Jacob and Fauchet using a more precise method for evaluating enhanced fracture repair. Tritiated thymidine autoradiography offers a simple and efficient method for estimating in any given cell population the number of cells which are capable of synthesizing DNA at a given time and of undergoing mitosis afterwards[5,6].

Sixty, 6-months-old, female mice of a Brookhaven National Laboratory Swiss albino strain, having an average weight of 30 gm., were used in the experiments. The mice were divided into three groups, namely:

Group A. (12 mice.) The left femur was fractured at mid-shaft by digital pressure while the animal was under ether anæsthesia. Six mice were killed 1 week after fracture and another six at 2 weeks. These animals served as normal controls.

Group B. (12 mice.) The left femur was fractured as in Group *A*. This group received a daily subcutaneous injection of 0·25 ml. of herring-milt DNA (20 mgm./ml. diluted 1 : 10 with sterile physiological saline). A total dose of 0·5 mgm. DNA/day was administered for 7 days and then the animals were killed, 35 days after the first injection. This group served as a control against the possibility of the formation of duodenal adenocarcinoma. Immediately after death, the entire gastrointestinal tract was removed, opened, and examined along its entire length with a stereoscopic microscope.

Group C. Consisted of 36 mice. The left femur of each was fractured at mid-shaft and the mice were then subdivided into three groups, receiving 5, 10 and 20 mgm. of DNA/day in a single dose, respectively. One group of 6 mice was given 5 daily doses and killed at the seventh day. Another group of 6 was given 10 daily doses and killed after 14 days. (The DNA preparation was supplied by E. Fougera and Co., Inc., Hicksville, New York.)

The animals in Groups *A* and *C* received 0·5 μc. tritiated thymidine subcutaneously 1 hr. prior to death. The femora were fixed in cold, buffered formalin for 24 hr., washed in running tap-water for an additional 24 hr., and decalcified in a 10 per cent solution of disodium versenate. Paraffin blocks were prepared and sections cut at 5μ. One set of sections was stained routinely with hæmatoxylin and eosin, and two sets were used for autoradiographic preparations. These sections were covered with Kodak NTB_3 liquid emulsion and exposed for 16 days in a cold, dry atmosphere. The emulsions were developed then stained with hæmatoxylin.

Group A. Histological sections of this group revealed the classical picture of fracture repair. One week after fracture, the callus was essentially made up of chondrogenic cells. Some cartilage formation and early bone formation was seen at the periphery of the callus. At the edge of the fragments, early bone formation was taking place. Two weeks following the fracture, the large callus consisted essentially of cartilage, and new trabecular bone formation was seen at its periphery. Extensive bone formation was also seen at the edges of the fragments as the cartilaginous mass was being replaced.

Autoradiographs revealed extensive labelling of periosteal osteogenic cells about the fracture site. Osteoblasts, lining the newly formed trabeculæ and those present in regions where cartilage cells were being replaced by trabecular bone, were highly labelled. Fibroblasts and chondrogenic cells comprising the population of the fracture callus were frequently labelled.

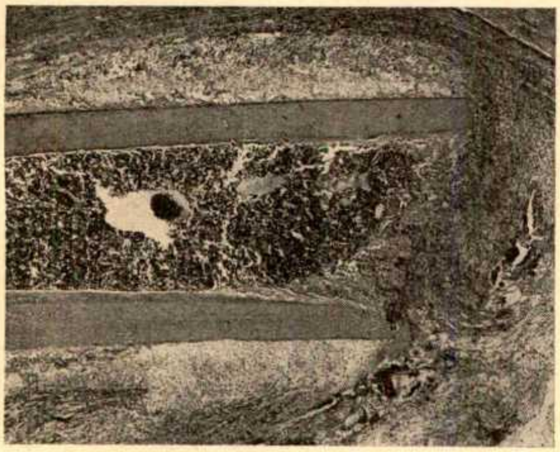

Fig. 1. A fractured femur 7 days after trauma and daily treatment with 10 mgm. herring-milt DNA. Hæmatoxylin and eosin stain. (×22·5)

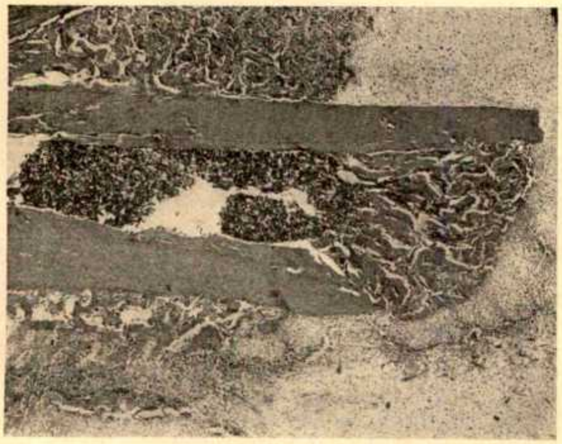

Fig. 2. A fractured femur 14 days after trauma and daily treatment with 10 mgm. herring-milt DNA. Hæmatoxylin and eosin stain. (×22·5)

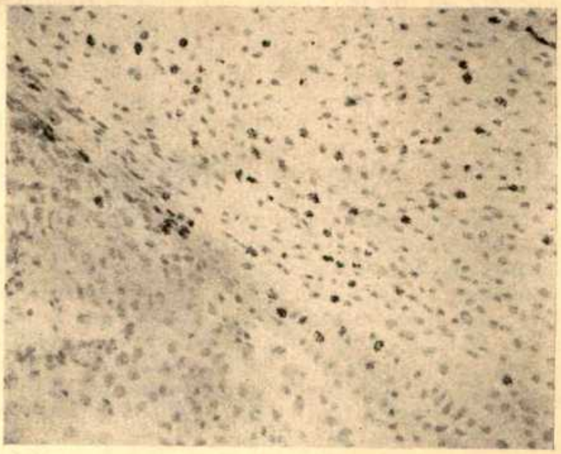

Fig. 3. An autoradiograph of a 7-day fractured femur treated daily with 10 mgm. herring-milt DNA. The photomicrograph was taken from a region of active cell proliferation and osteogenic cell transformation into cartilage cells. Although labelling is extensive, it does not represent an increase over the non-treated controls when similar areas are evaluated. Hæmatoxylin stain, ×150

Group B. Examination of the entire gut along its length with a stereomicroscope revealed neither pathology nor local hyperæmia. The gut appeared grossly normal. No pathology was seen in any of the groups.

Group C. The histological sections in this experimental group which were treated with herring DNA revealed a similar picture at 1 and 2 weeks after fracture as that found in the control Group *A* (Figs. 1 and 2). Cartilaginous callus was abundant at 2 weeks and the replacement of the callus by bone was not increased over the controls.

Autoradiographs exhibited an extensively labelled periosteum, especially at the fracture site. Numerous labelled fibroblasts and mesenchymal cells were observed. The results were similar to the controls (Fig. 3).

It has long been known that most animals do not require exogenous sources of purines and pyrimidines to meet the needs of the organism in synthesizing DNA. Dietary ammonia nitrogen was shown by Barnes and Schoenheimer[7] to be readily utilized by rat tissues in the synthesis of the purines and pyrimidines of nucleic acids. Subsequent experiments revealed that simple carbon compounds (for example, carbon dioxide, glycine, formate), served to supply the carbon atoms necessary for the synthesis of nitrogenous bases. It appears that the animal body can synthesize the necessary heterocyclic compounds at a rate which meets the needs of the organism. It is obvious that during the process of skeletal repair, an abundant supply of DNA precursors is necessary. Perhaps an adequate supply of precursor material is not available during fracture repair in older animals resulting in prolonged repair. DNA or its breakdown products which are not normally essential components for nucleic acid synthesis might under such conditions be utilized and thus result in enhanced fracture repair. Contrary to the findings of Jacob and Fauchet, our results did not show, in any of our animals, gross or microscopic evidence of enhanced fracture repair after parenteral administration of 5, 10 and 20 mgm. of herring-milt DNA and observing fractures for 1 and 2 weeks after trauma. The autoradiographs also failed to show stimulation of cell proliferation following treatment. Moreover, prolonged DNA treatment did not result in the production of adenocarcinoma of the gut or other pathology.

LINKAGE OF SIALIC ACID IN THE HUMAN ERYTHROCYTE ULTRA-STRUCTURE

By G. M. W. COOK

Department of Radiotherapeutics, University of Cambridge

THE sialic acids (*N*-acylated neuraminic acids) have been shown to be present in many mammalian tissues[1] and in bacteria[2]. In the human being, sialic acid is present in serum proteins, seminal fluid, cerebrospinal fluid and in red cells. In human red cell stroma Bial's colour reaction suggests the presence of about 1 per cent of neuraminic acid[3], and it has been found that the sialic acid liberated from human erythrocyte stroma following receptor-destroying enzyme (RDE) treatment was *N*-acetyl neuraminic acid (NANA) (ref. 4). Recently it has been shown that bound sialic acid is liberated as a sialomucopeptide from the human erythrocyte[5] following treatment with trypsin[6,7] and, using RDE (ref. 8), that the carboxyl group of a sialic acid is the dominant ionogenic group present at the surface of the human erythrocyte.

Besides contributing to the negative charge of the human red blood cell membrane, sialic acid has been shown to be associated with the M and N receptors of this cell[9]. Recently, Romanowska[10] has studied the products of mild acid and alkaline hydrolysis of M and N blood group preparations, obtained by phenol extraction of human erythrocyte stroma, and concluded that *N*-acetyl neuraminic acid may be combined with galactose or *N*-acetyl hexosamine in these biologically active materials. It is thus possible that these disaccharides form an essential part of the prosthetic group of M and N mucoids.

Since trypsin treatment destroys M and N antigenic characteristics of erythrocytes[9,11], it seems very likely that the released sialomucopeptide is closely associated with the M and/or N antigenic configuration, especially as sialic acids have been shown to have inhibitory properties towards anti-M and anti-N agglutinins[11]. In view of this and the interest in sialic acid as an important constituent of other animal cell membranes[12,13] it was decided to investigate further the nature of the carbohydrate moiety of this sialomucopeptide. Mild acid hydrolysis (0·5 *N* hydrochloric acid at 105° C. for 16 hr.) failed to show the presence of neutral sugars. However, more vigorous hydrolysis (6 *N* hydrochloric acid at 105° C. for 15 hr.) liberated large quantities of galactosamine in addition to eight different amino-acids (leucine (or isoleucine) threonine, alanine, glycine, arginine and glutamic acid and as yet two unidentified amino-acids in trace quantities). The sialosubstance would therefore appear to consist of sialic acid, galactosamine (or an acyl derivative) and an aliphatic peptide chain. Sulphur-containing amino-acids were not detected in hydrolysates of this mucosubstance.

Work on the sialosubstances has shown that sialic acid regularly occurs together with hexosamine[14] and the structures of two sialic acid-containing compounds have been elucidated, namely, milk oligosaccharide (sialyl-lactose (α-D-sialyl (2–3) β-D-galactopyranosyl (1–4) D-glucopyranose)) and the prosthetic group of bovine salivary mucoprotein (BSM), (6-α-D-sialyl-*N*-acetyl galactosamine)[15]. In view of the general analysis of the sialomucopeptide under investigation and the presence of sialic acid in BSM and associated with the disaccharides described by Romanowska, a reasonable structure for the carbohydrate moiety of this sialomucopeptide would be 6-α-D-sialyl-*N*-acetyl galactosamine. This possibility was investigated using RDE and mild alkali (treatments which degrade the carbohydrate in preference to the protein) on samples of the sialomucopeptide and a sample of purified BSM (refs. 16 and 17) used as a model. BSM is believed to consist of a protein core surrounded with *N*-acetylgalactosamine units with external end groups of sialic acid[15].

Samples of sialomucopeptide[5] were examined by paper electrophoresis[18] and those which contained only trace contaminants (di- and tri-peptides) were freeze-dried and stored under nitrogen at –25° C.

Alkaline hydrolysis of sialomucopeptide. Mucosubstance (1–2 mgm.) was treated with saturated barium hydroxide solution. The mixture was kept at 80° C. for 15 min., cooled under tap-water and acidified with *N* sulphuric acid to *p*H 6. The mixture was then centrifuged, the clear supernatant reduced to a small volume at room temperature on a watch glass in a vacuum desiccator over potassium hydroxide, and examined by paper chromatography.

Alkaline hydrolysis of bovine salivary mucoprotein. BSM (27·0 mgm.) dissolved in distilled water (5 ml.) was treated with saturated barium hydroxide solution (2 ml.) using the same procedure as already outlined except that the hydrolysate was dialysed against twice distilled water at 4° C. and the dialysate then lyophilized. The residue thus obtained was taken up in a few drops of distilled water for examination by paper chromatography.

Preparation of chromogen I and chromogen III. *N*-acetyl hexosamine (200 mgm.) was treated with 0·02 *N* barium hydroxide solution using the hydrolysis technique already described. The lyophilized dialysate was examined by paper chromatography (Whatman No. 1 paper, butan-1-ol/pyridine/water 6 : 4 : 3 v/v descending solvent[15]). Development with Ehrlich reagent showed the presence of chromogen I (anhydro-*N*-acetyl hexosamine). A quantity of chromogen I (6 mgm.) was treated with 0·1 *N* sodium carbonate solution (1 ml.) at 80° C. for 30 min. and then cooled and brought to *p*H 6 with 0·1 *N* hydrochloric acid solution. After electrolytic desalting and reduction of volume under reduced pressure paper chromatography showed the presence of chromogen I and chromogen III (5-dihydroxyethyl-3-acetamidofuran) in the solution This mixture, which was stored at $-25°$ C, was used as a standard marker mixture in the subsequent paper chromatography[15]

The various components present on the chromatograms were detected using characteristic reactions Where necessary the paper was cut into various strips if more than one reagent was to be used *N*-acetyl neuraminic acid was detected using orcinol–trichloroacetic reagent[8] Chromogens I and III were detected using Ehrlich reagent (*p*-dimethylamino benzaldehyde (500 mgm) dissolved in a mixture of ethanol (15 ml) hydrochloric acid (15 ml conc), butan-1-ol (90 ml) in the cold. Other components (hexosamines) were detected using indirect Ehrlich reagent This involved pre-treating the strip with alkaline acetyl-acetone reagent (reagent I· acetyl acetone (b p 138°–140° C (0 5 ml) in butan-1-ol (50 ml), reagent II aqueous potassium hydroxide (5 ml. 50 per cent v/v) in ethanol (20 ml). Reagent II (1 ml) was mixed with reagent I (20 ml) a few minutes before use and then the strip heated at 105° C for 5 min before treating with Ehrlich reagent at 90° C for 5 min

Paper Whatman No 1 Solvent, butan-1-ol/pyridine/water (6 4 3 v/v)

Paper chromatography of the alkali-treated mucopeptide showed the presence of a compound of low R_F value giving a reddish purple colour with indirect Ehrlich reagent, typical of sialyl-*N*-acetylgalactosamine[15] (Fig 1) contaminated with peptide which, being immobile in the solvent (Fig 2), caused a slight brown discoloration on the lower edge Spots corresponding to galactosamine and chromogen I were also detected Similar results were obtained after alkaline treatment of BSM (Fig 3) Free *N*-acetyl neuraminic acid was detected[19] in acid hydrolysates (0 1 *N* sulphuric acid at 80° for 1 hr) of both erythrocyte mucopeptide and from sialyl *N*-acetylgalactosamine (prepared as an eluate from chromatogram of alkali-treated BSM (Fig 3) and also following RDE treatment, thereby indicating that the sialic acid in the sialomucopeptide was linked terminally and α-ketosidically Direct quantitative determination of hexosamine[20,21] after acid treatment was not possible in view of the small amounts available Since hexosamines and their *N*-acetyl derivatives have been shown not to interfere with the estimation of sialic acid by Warren's method[19] one can calculate the amount of hexosamine, assuming that the ratio of sialic acid to hexosamine in erythrocyte sialomucopeptide is the same as that in sialyl-*N*-

M, marker mixture of chromogens I and III developed with Ehrlich reagent in the cold, *D*, sample of NANA containing *N*-glycolyl neuraminic acid developed with orcinol reagent, 1*H*, alkaline hydrolysate of BSM developed with orcinol reagent and showing presence of sialyl-*N*-acetyl galactosamine, 2*H*, alkaline hydrolysate of BSM developed with indirect Ehrlich reagent and showing presence of sialyl-*N*-acetvl galactosamine, very slight trace of *N*-acetyl galactosamine, and a trace of chromogen I, *H*, alkaline hydrolysate of BSM, untreated Region corresponding to sialvl-*N*-acetyl galactosamine eluted for further experiments

Paper Whatman No 1 Solvent, butan-1-ol/pyridine/water (6 4 3 v/v)

acetyl galactosamine Mixtures of sialic acid (*N*-acetyl neuraminic acid) and galactosamine were made up, the amounts present being calculated as already explained The mixtures were then subjected to the same acid treatments as the sialomucopeptide before evaluating optically the chromophore produced by such a mixture in the Rondle Morgan hexosamine determination The same type of experiment was performed using the eluate of sialyl-*N*-acetyl galactosamine In all these experiments there was good agreement between the actual optical density reading in the experiment and the predicted optical density reading obtained from standard mixtures

The foregoing experiments suggest that sialic acid present in a sialomucopeptide liberated by the action of trypsin on the human red blood cell ultrastructure is linked α-ketosidically to a galactosamine (most probably the *N*-acetyl derivative judging from the presence of chromogen I in the hydrolysate) residue in an alkaline labile saccharide moiety Comparing the behaviour in the above experiments of erythrocyte sialomucopeptide with that of BSM, a known source of 6-α-D-sialyl-*N*-acetyl galactosamine[15], it would appear that the saccharide moiety (or moieties) in this mucopeptide is of similar structure to the prosthetic group of BSM From Romanowska's work[10], it is evident that such a chemical structure is of possible importance in the M and N blood group substances as well as *N*-acetylneuraminyl-galactose It is therefore interesting that a mucosubstance liberated from the native red cell by trypsin, which results in the concomitant loss of some of this cell's M and N character[11]), contains a chemical structure similar to that in the M and N mucoids obtained by phenol extraction of human erythrocyte stroma Further, this result lends weight to the suggestion[5] that structures analogous to those present in ovine submaxillary gland mucoprotein[22] are an important feature of the architecture of the human red blood cell ultrastructure

I thank the Medical Research Council for financial assistance, Dr. D H Marrian for his advice on the preparation of the manuscript, Prof J S Mitchell, Dr D. H. Heard and Dr G V F Seaman for their interest in this work I also thank Prof Ward Pigman for a gift of purified BSM and Mr E. W. Mitchell and Miss C A Cavanagh for preparing the chromatograms for photography.

AEROBIC RESPIRATION IN SOIL CRUMBS

By Dr D J. GREENWOOD and G. BERRY

National Vegetable Research Station, Wellesbourne

In previous work[1] a theory was developed to relate the aerobic respiration-rates of spherical soil crumbs to their size and the oxygen partial pressure surrounding them The object of this communication is to correct an error in the formulation of the theory and to extend it to describe the respiration-rates of irregular non-spherical crumbs

Consider a sphere of soil saturated with water and containing a uniform distribution of micro-organisms Let M be the aerobic respiration-rate Then M can be taken[1] as constant and independent of oxygen concentration for $C \geqslant C_0$ and zero for $C < C_0$ Suppose the oxygen concentration is C at a distance r from the centre of a sphere of radius R_1 and D is the diffusion constant of oxygen through the sphere Then for the stationary state

$$\frac{D}{r}\frac{\partial^2(rC)}{\partial r^2} = M \qquad (1)$$

The boundary conditions are

$$C = C_1 \text{ for } r = R_1$$

$$\frac{\partial C}{\partial r} = 0 \text{ for } r = R_0$$

where the sphere is anaerobic for $r < R_0$ so that $C = C_0$ for $r = R_0$

On solving (1) and putting $r = R_1$ we have

$$6D(C_1 - C_0) = M(R_1^2 + 2R_0^3/R_1 - 3R_0^2) \qquad (2)$$

By polarographic techniques similar to those used by Longmuir[2] we found that the respiration-rate of soil and yeast organisms did not decrease by lowering of the oxygen concentration until very low values were reached The oxygen concentration causing a 50 per cent inhibition of respiration was about 5×10^{-6} M Hence, as a close approximation we have

$$6DC_1 = M(R_1^2 + 2R_0^3/R_1 - 3R_0^2) \qquad (3)$$

By taking K as the respiration-rate expressed per unit of total volume including the part in which $C < C_0$

$$6DC_1 = MR_1^2(3 - 3(1 - K/M)^{2/3} - 2K/M) = MR_1^2 f(K/M) \text{ say} \qquad (4)$$

this equation replaces equation (4) of the previous paper[1]

If Penman's[3] formula $D = 0\ 66D_0S$ (where S is pore space and D_0 is the diffusion constant of the material in the pore space) holds for liquids as well as for gases equation (4) becomes

$$3\ 96D_0SC_1 = MR_1^2 f(K/M) \qquad (5)$$

Since other work[4] suggests that the interfacial resistance between the liquid and the gas phase is small, C_1 can be taken as the oxygen concentration in water which is in equilibrium with the oxygen partial pressure surrounding the crumbs

Equation (5) was tested by measuring the respiration-rates of moist moulded spheres of soil (radius 0 3–0 5 cm) when they were surrounded with oxygen partial pressures between 0 and 16 cm of mercury The results are shown in Fig 1 C is in cm of mercury, S and R^2 were calculated from weight, specific gravity, and moisture content determinations by assuming that the pore space was completely filled with water and that there were no gas-filled pores For equation (5) to hold the points in the figure should fit on a straight line passing through the origin Since the diffusion constant of oxygen through water calculated from the gradient of the line is $2\ 6 \times 10^{-5}$ cm ^{2} sec $^{-1}$ and that quoted by Millington[5] is $2\ 38 \times 10^{-5}$ cm ^{2} sec $^{-1}$ it appears that equation (5) is approximately valid

Surface areas of different-sized crumbs obtained from sieved soil were determined by measuring the mean chord-lengths on random transects through the crumbs If t is the mean chord length, A the surface area and V the volume of the crumb, which is assumed to be approximately convex, then t is equal to $4V/A$ (ref 6) The mean value obtained for the shape factor $A/V^{2/3}$ was 6 06 compared with 4 84 for a sphere

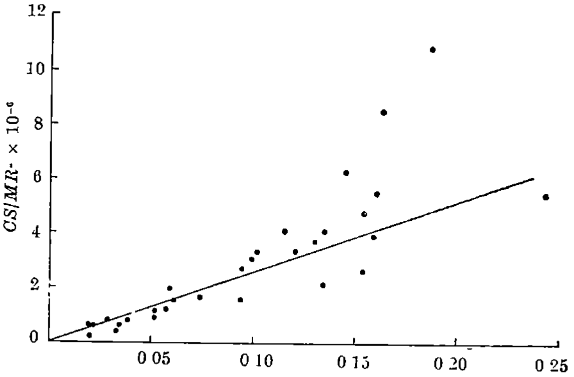

Fig 1

Soil aggregates of irregular shape and spheres having the same A/V ratios might be expected to have similar diffusion characteristics Thus, for any irregular shape we can define an equivalent spherical radius given by $R_1 = 3V/A$ Substituting in equation (4) we have

$$2DC_1A^2 = 3MV^2 f(K/M) \qquad (6)$$

It was hoped to test the validity of this equation by cutting or moulding shapes of soil to known A/V ratios and then finding the effect of oxygen partial pressures on their respiration-rates However, with such a technique there were large variations in replicate determinations of K/M Because we found that the effect of oxygen concentration on the respiration of yeast was similar to its effect on the respiration of soil organisms, errors were minimized by using shapes prepared from agar, yeast and nutrient solution (2 per cent glucose, 0 1 M phosphate buffer pH 6 8) in place of shapes prepared from soil For each of the different shapes, the points obtained by plotting $f(K/M)$ against C gave a good fit to a straight line passing through the origin Values for D were calculated from the gradient of the straight lines, the A/V ratios, and equation (6) by taking the solubility of oxygen in agar to be the same as in water If equation (6) were correct the values for D obtained with the different shapes would be the same irrespective of their different shape factors Table 1 shows that for a limited number of shapes the diffusion constants were roughly independent of shape factor Thus the table, when taken in conjunction with the shape factor determinations on soil crumbs, provides limited evidence that the equation applies to the shapes found in soil

Table 1. Estimated Diffusion Constants of Agar Shapes

Material	$A/V^{2/3}$	$D \times 10^5$
Agar shapes	6 47	1 20
,, ,,	5 70	1 07
,, ,,	5 69	1 02
,, ,,	5 54	0 99
,, ,,	6 57	1 08
Soil crumbs	6 06	—
,, spheres	4 84	—

Previously reported measurements[1] of the aerobic respiration-rates of soil crumbs of 2–4 mm diameter when moistened in Warburg flasks and maintained under different oxygen partial pressures were lower than those obtained theoretically from equation (6) It may be that in the theoretical determinations, since no account was taken of any reduction in the surface area of the crumbs by contact of the crumbs with each other and the bottom of the flasks, the values that were taken for the surface areas were too high, and, in consequence, the values for K/M were also too high

FLAVONOID PRODUCTION BY MATURE CITRUS FRUIT TISSUE PROLIFERATING *IN VITRO*

By Dr. HERBERT A KORDAN and Dr L MORGENSTERN

Department of Surgery, Cedars of Lebanon Hospital,
Los Angeles

FLAVONOID compounds of higher plants have received considerable attention from diverse fields of study[1-9] Their biological role, however, is for the most part unknown[2,7,10] with the possible exception of lignin formation[7] and attracting insects for pollination[2,7,10]

Vesicle stalks from mature lemon fruits (*Citrus limon* (L) Burmann, var Eureka) proliferating *in vitro*[11] frequently release a white water-insoluble material to the external medium Sub-cultures and straight transfers of proliferating tissue invariably release this material in noticeable quantities This article presents evidence that the water-insoluble material contains flavonoids which are continually synthesized by the proliferating tissue.

Mature lemon fruits contain the flavanone glycoside hesperidin[12] which behaves like a true ketone forming oximes, phenylhydrazones, dinitrophenylhydrazones, ketazines and semicarbazones[13] On the basis of this information, ethyl alcohol (95 per cent) extracts of normal non-proliferating vesicle stalks, senescing non-proliferating stalks, proliferating stalks and alcoholic solutions of nutrient medium containing the water-insoluble material were subjected to a 2,4-dinitrophenylhydrazine test for carbonyl compounds (Table 1)[14] The results in Table 1 indicate that the water-insoluble material contains a carbonyl group(s) and that it was derived solely from the proliferating tissue Autoclaved freshly prepared nutrient solution gave a negative test with the carbonyl reagent as did ethyl alcohol alone (controls) The largest quantity of extractable material was obtained from the proliferating tissue whereas the largest amount of dinitrophenylhydrazone derivative was obtained with the water-insoluble material present in the nutrient medium which had supported the growth of sub-cultures and transfers of proliferating tissue The quantitative increase in the carbonyl compound(s) appear to be the result of growth of tissue rather than senescence

Living non-proliferating vesicle stalks are translucent in appearance When exposed to ammonia vapour from concentrated aqueous ammonium hydroxide solutions, the tissue becomes a bright yellow in colour Proliferating tissue also turns bright yellow when exposed to ammonia fumes This test is sensitive to polyphenolic carbonyl compounds represented by flavones, flavanones, chalcones and xanthones[2] The addition of concentrated ammonium hydroxide to nutrient solution containing the water-insoluble material causes the immediate production of a yellow solution which fluoresces markedly under short-wave ultra-violet light (253 mμ) The addition of 1 0 N sodium hydroxide to the medium results in the same effect as obtained with ammonium hydroxide The appearance of a yellow coloration on the addition of alkali can serve as a substitute for the ammonia test described here[2] The positive test with ammonia on proliferating tissue demonstrates that a flavonoid compound(s) is continually synthesized by the growing tissue The positive alkali test indicates that the water-insoluble material contains a flavonoid(s) the same or similar to those present in the normal and proliferating tissue

The addition of 0 5 ml of 95 per cent ethyl alcohol to each vial containing nutrient solution plus the water-insoluble material results in the complete solution of the latter A number of qualitative colour reactions for flavonoid compounds[2] were performed on the ethyl alcohol solutions containing the unknown(s) In all cases, ethyl alcohol solutions of freshly prepared and autoclaved nutrient medium

Table 1 Results of the 2,4-Dinitrophenylhydrazine Test for Carbonyl Compounds

Autoclaved freshly prepared medium*	—

* Controls

Note —=Negative reaction, +=positive reaction +=quantity present in normal tissue +3=three times the normal, +5=five times the normal

Table 2 Colour Tests for Flavonoid Compounds

Test solution	Reagent	Reaction	Colour
Alcohol + unknown	HNO_3 (con)	+	Blue-green
,, + medium*	,,	−	Colourless
,, + unknown	NH_4OH (con)	+	Yellow
,, + medium*	,,	−	Colourless
,, + unknown	NaOH (1 0 N)	+	Yellow
,, + medium*	,,	−	Colourless

* Controls consist of 95 per cent ethyl alcohol plus freshly prepared autoclaved nutrient medium

Con , concentrated acid or base , − =negative reaction , + =positive reaction

plus the test reagent served as controls Three tests were always positive for flavonoids (Table 2)

A spot of ethyl alcohol solution of the unknown placed on Whatman No 1 filter paper sheets (10 in × 10 in square) fluoresces strongly under short-wave ultra-violet Exposure of the spotted paper to ammonia fumes markedly increases the fluorescence of the spot. Two-dimensional ascending paper chromatography[15] of the ethyl alcohol solution, using water saturated with *n*-butanol plus ammonium hydroxide to *p*H 11 as the solvent for the first run and water saturated with *n*-butanol as the solvent for the second run, reveals five fluorescent spots (Fig 1) Fluorescence of the spots is increased by exposing the chromatogram to ammonia fumes An alcohol extract of normal non-proliferating stalks spotted on chromatographic paper is non-fluorescent. The addition of alkali to the alcohol solution results in the immediate production of a yellow solution which is strongly fluorescent Autoclaved freshly prepared nutrient solution (control) is non-fluorescent

Living normal non-proliferating vesicle stalks as well as other tissues of the mature lemon fruit do not exhibit fluorescence under short-wave ultra-violet The living proliferating tissue *in vitro*, however, manifests marked spontaneous fluorescence This capacity for spontaneous fluorescence appears to be restricted to the dividing and/or growing cells Living non-dividing regions of a proliferating stalk appear as non-fluorescent material Fluorescence of the proliferating tissue demonstrates that the material released to the medium is produced by the dividing and/or growing cells

Stems and roots of germinating seeds of lemon, citron (*Citrus medica* (L)) and sour orange (*Citrus aurantium* (L)) are spontaneously fluorescent under short-wave ultra-violet light Two-dimensional chromatography of alcoholic extracts of the intact stems of citron and sour orange seedlings using the solvent systems described here reveal fluorescent spots, some of which appear to be the same or similar to those from the proliferating fruit tissue (Figs 1, 2 and 3)

The relationship between tissue fluorescence and cell division and growth in the present *in vitro* system is not known It is interesting to note, however, that synthetic carcinogens such as 3,4-benzpyrene, 3-methylcholanthrene and other chemically related compounds and a number of plant growth regulators[9] are fluorescent compounds. Further studies on the nature of this water-insoluble material and the flavonoids and their relationship to the spontaneous growth of mature citrus fruit tissue *in vitro* are in progress

This work was supported by a grant from the National Institutes of Health and Cedars of Lebanon Hospital Surgical Research Funds

LETTERS TO THE EDITOR

RADIOPHYSICS

Brightness Distribution of the Radio Source 14*N*5*A*

MANY radio sources are now known to have brightness distributions differing markedly from a radially symmetrical gaussian distribution[1,2] Consequently the detailed investigation of individual radio sources by long baseline measurements has become particularly significant The normal techniques which involve the moving of an outstation aerial to many sites at distances comparable with the maximum length of the baseline are difficult to apply with baselines of the order of 100 km A further extension has therefore been made of the tracking technique[3,4] in which the motion of the source across the sky is used to change the effective length of the baseline and its position angle relative to the source This communication describes the investigation of the radio source 14*N*5*A* by this method This source is of particular interest since it is the most distant source to be identified with an optical object

The observations were made with the 250-ft radio telescope at Jodrell Bank together with a small steerable broadside array having a collecting area of 36 m.² at the distant station These were used in conjunction with equipment which continuously adjusted phase and compensating delay and so enabled fringes to be obtained without interruption for a period of several hours The results of the observations on the radio source 14*N*5*A* are shown plotted against hour angle in Fig 1, where the flux scale has been derived on the assumption that the source 3*C* 48 is unresolved at 61,100λ and has a flux density of 50×10^{-26} W m.$^{-2}$(c/s)$^{-1}$ at the observing frequency of 158·6 Mc/s

When a radio source is observed for a period of many hours using an interferometer with a baseline which is nearly east–west and horizontal, it can be shown that the results are equivalent to observations of the source in the zenith with an interferometer, one aerial of which is fixed while the other is moved continuously along an elliptical path The particular ellipse obtained for the radio source 14*N*5*A* with the present baseline is shown in Fig 2 in which the dimensions are in wave-lengths and the fixed aerial is at the origin If results were available from many different baselines a contour map of fringe amplitude could be plotted on this diagram and then the results in Fig 1 would represent a section along the ellipse through these contours It is found that the contour diagrams calculated for any source model consisting of a single component, even if this is an elliptical ring, cannot lead to the results shown in Fig 1, and it is necessary to resort to a two-component model If the components are of equal intensity and of negligible size the contour diagram which could be plotted on Fig 2 consists of parallel 'ridges' of high fringe amplitude which are separated by 'valleys' of zero fringe amplitude One of the ridges must pass through the origin and if this ridge can be identified at its crossing of the ellipse, the major axis of the source is defined approximately The maximum at an hour angle of 20 hr cannot be the origin ridge because the maximum at 3 hr would then be closer to a valley than its observed amplitude would allow The maximum at 3 hr must therefore come from the origin ridge and, since the zeros are symmetrical about the origin they must lie along the dotted lines shown in Fig 2 Thus the two components must be 4″ of arc apart in position angle 135° Then to account for the large fringe amplitude at 20 hr compared with the smaller one at 3 hr the components must be less than 1″ of arc along a line joining them but 1·7″ of arc in length perpendicular to this line

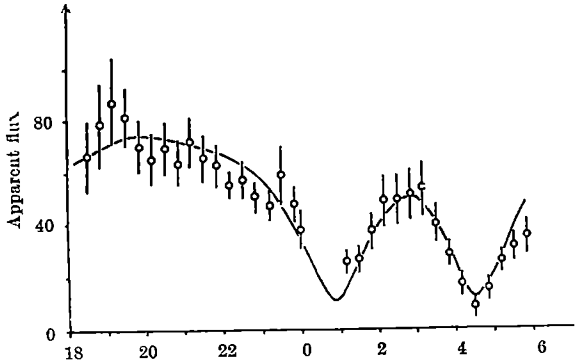

Fig 1. Observations of the radio source 14*N*5*A* at different hour angles, with an interferometer of aerial separation 61,100λ Each point is the mean value over 20 min with its standard deviation

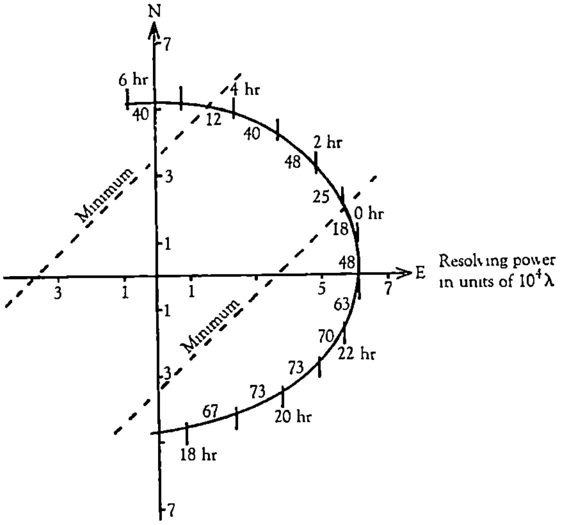

Fig 2 A diagram showing the resolving power, at different hour angles of observation, of an interferometer with aerials 61,100λ apart The elliptical line is the path followed by the tip of a vector from the origin, the direction of which gives the position angle of the base-line relative to the source 14*N*5*A* The length of this vector is proportional to the effective resolving power in that direction The figures outside the elliptical line give the hour angle of observation, while the figures within the line are computed values of fringe amplitude for the double source model proposed

The curve shown in Fig 1 is the calculated fringe amplitude for this model with the major axes of the components perpendicular to the line joining them and the flux from one component equal to two-thirds of the flux from the other

The radio source 14*N*5*A* has been identified with the brightest member of a very distant cluster of galaxies[5] with a red-shift ($d\lambda/\lambda$) of 0 47 Thus, assuming Hubble's constant to be 100 km /sec /Mps , and assuming a cosmological model, the projected component sizes can be calculated[6] and are given in Table 1

Table 1 PROJECTED DIMENSIONS OF 3C295 FOR TWO COSMOLOGICAL MODELS

	Steady state	Einstein—de-Sitter
Component separation	20 kps	16 kps
Major axis of component	8 kps	7 kps

The corresponding calculations for the Cygnus-*A* source give 69 kps for the component separation and 35 kps for the length of the major axes of the components, these values being nearly independent of the cosmological model assumed Thus it is seen that the projected size of the Cygnus-*A* source is between 3 5 and 4 5 times the projected size of the source 14*N*5*A* There is also the further difference that the major axes of the components of the Cygnus source are parallel to a line joining the two components It is possible to construct many three-dimensional source models each of which, when observed in different orientations, will appear similar both to Cygnus-*A* and to 14*N*5*A* For example, two parallel cigar-shaped components each 37 kps long inclined at an angle of 20° to the line joining their centres would resemble Cygnus-*A* when observed along a direction in the plane of the source, and 14*N*5*A* from a direction above this plane when observed at a small angle to the line joining the components The appearance of the source changes rapidly as the direction is altered in this latter case, and hence there is a low probability that this interpretation is correct It seems more likely that there are real differences in the structure of these two sources and these would appear to be large enough to mask cosmological effects, even with recessional velocities up to half the velocity of light

We thank L R Allen for help with these observations and the maintenance of the equipment for the baseline of 61,100λ We wish also to acknowledge the award of a Leverhulme fellowship (B R) and a Department of Scientific and Industrial Research maintenance grant (B A)

PHYSICS

Charge Ratio of High-Energy Cosmic Ray Muons

RESULTS are given in this communication of the ratio of the number of positively charged to negatively charged muons in the vertical cosmic radiation at Durham (200 ft above sea-level), in the momentum range 5–1,000 GeV /c The measurements were made with the Durham cosmic ray spectrograph which consists of a large electromagnet with layers of Geiger counters and neon flash-tubes as the detecting elements[1,2] The measurements used in the present analysis were made by us as part of our work on the determination of the high-energy spectrum[2], the results refer to the period November 1959–March 1960 Instrumental bias was reduced by operating with frequent reversals of the magnetic field

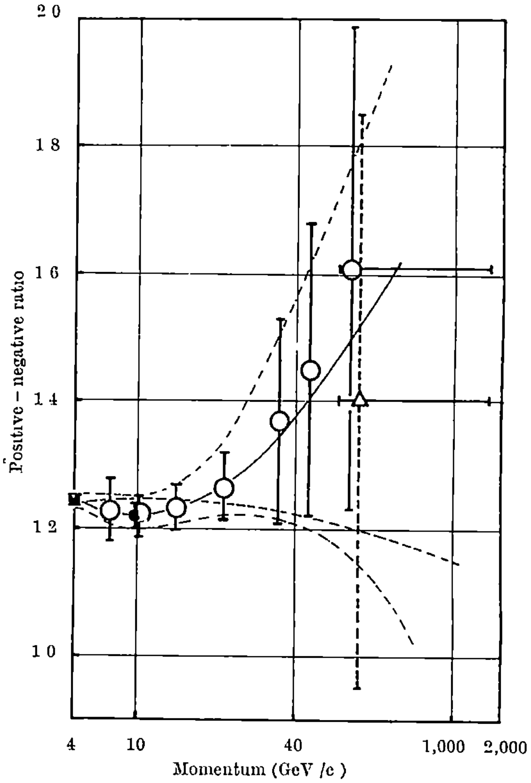

Fig 1 The measured charge ratio of muons ——, best line, – – –, confidence limits, – – –, pion fluctuation model, ●, Geiger counter data, ○, △, flash-tube data

The results on the charge ratio are given in Fig 1 and Table 1 Those in Table 1 and most of the results in Fig 1 refer to observations with the flash-tube arrays With the exception of the two ratios at the highest momentum the values are all independent The ratio shown with a dotted error line is derived from a restricted sample of the particles in the highest momentum band, selected so as to give the highest attainable accuracy in momentum determination For these particles the maximum detectable momentum is 657 ± 112 GeV /c

Small corrections have been applied for the effect of protons using the results of Brooke *et al* [3], the maximum correction to the ratio is 1 2 per cent at 6 7 GeV /c Further corrections, allowing for random errors of measurement, are significant only at the highest momentum where they amount to increases of

Table 1 THE MEASURED CHARGE RATIO OF MUONS

Median momentum (GeV /c)	Charge ratio	Statistical error (*S D*)
6 7	1 229	0 049
10 4	1 223	0 038
17 5	1 233	0 037
35	1 268	0 051
77	1 37	0 16
120	1 45	0 23
240 *	1 61	0 38
240 *	1 40	0 45

* The measurements made at this momentum have been made by two different methods and are not statistically independent

11 and 6 per cent in the ratio measured by the two methods

Also shown in Fig 1 are the ratios for the two highest momentum categories for which the Geiger counter data were used Since these results come from a previous experiment carried out by Gardener *et al* [4], in the period March–September 1958 they can be regarded as largely independent of the present results There is good agreement over the common momentum-range

An attempt is made in Fig 1 to show confidence limits, based on the statistical standard deviation, outside which it would appear that the ratio is unlikely to lie The line giving best fit to the data is also shown, and this indicates a continuous increase in the ratio with increasing momentum

Comparison of the present work with other results (for example, the review of Holmes *et al* [5]) shows that there is general agreement up to about 20 GeV /c Above this momentum most other measurements are of lower statistical accuracy, having come from instruments of lower momentum resolution The measurement at the highest momentum reported previously is that of Holmes *et al* [5], in which a ratio 1 02 ± 0 14 at a mean momentum of 98 GeV /c was found, suggesting a much more rapid fall off than found here

The measured charge ratio can be used to give information on the nature of the interactions in which the parents of the muons are produced Two cases will be considered first, that the majority of muons come from pions which are generated directly in the interactions of the primary cosmic rays (or their secondaries), and secondly following a recent suggestion by Peters[6], that an intermediate hyperon plays a predominant part at high momenta

In the first case, an approximate analysis is made in which the effects of secondary collisions are neglected Assuming that the multiplicity, M, of pion production varies with the energy of the primary particle, E_p, as $M = BE_p^{\alpha}$, and, using mean values of B and α taken from direct measurement with nuclear emulsions, the predicted charge ratio of muons is derived This proves to be much nearer unity than observed The importance of fluctuations in multiplicity from one interaction to another has been noted by Pine *et al* [7], and detailed calculations have been made by Hayman[8] The calculations show that when allowance is made for the fluctuations, the predicted ratio is closer to the ratio observed in the range 5–10 GeV /c , although the predicted decrease in ratio with increasing momentum is still too rapid It is possible to obtain the variation shown in Fig 1 as the dotted line, which is just consistent with the observations, if it is assumed that the fluctuations in multiplicity become greater as the primary energy increases, there is in fact some evidence for such an increase in fluctuations from the emulsion results reviewed recently by Perkins[9]

The second case has been examined by Babu and Yash Pal[10], who have shown that the hyperon model predicts a charge ratio of 0 54 at 100 GeV /c and still lower values at higher momenta, that is, there is a negative charge excess Such predictions are inconsistent with the present data The same authors also point out that the negative excess probably could be removed if the probability of a Σ^+-hyperon emerging from a high-energy interaction were much greater than that for other hyperons

It is concluded that the present measurements of the charge ratio of muons at sea-level are consistent with a pion source in which the fluctuations increase with energy The results are inconsistent with the predictions of the hyperon model as originally proposed by Peters

We thank Prof G D Rochester for his interest in the work

Foundations of Relativistic Quantum Mechanics

THE fundamental role of Dirac's equation is well known, by demanding relativistic invariance of a first-order equation you get two of the most essential properties of a particle, namely, spin and the existence of an anti-particle So long as one thinks of groups acting on co-ordinate space no significant generalization of this formalism is possible in existing quantum theory

However if one examines the proof of invariance[1] the essential step consists in assuming that the infinitesimal transformation

$$x' = AxA^{-1}$$

on E_4, of the Lorenz group B_2, induces a transformation

$$\psi' = A\,\psi$$

on S_4, the space of spinors But this assumption is not necessary and even has the appearance of arguing in circles That is one could have just as well a larger group G acting on the combined space $E_4 + S_4$, leaving invariant a function $f(x, \psi)$ which could be considered the Lagrangian of a wave equation

In fact, it follows from a geometrical study of E Cartan[2], there is just one possibility for G, namely, the exceptional simple Lie group F_4 which acts as an orthogonal group on E_9 and also on its space of spinors S_{16} leaving invariant a trilinear form[3] $f(\chi, z, \psi)$

One may think that the 8 + 1 dimension is an embarrassment, but this is not at all the case since it is known that quantum mechanics admits a consistent interpretation as a group over classical phase space[4,5] in which some of the co-ordinates z have character of hidden variables As a consequence we get two additional spin characters for a particle (since F_4 is of rank 4). To see what they may be we have to note the property of F_4 which makes it unique.

The space S_{16} is the non-Arguesian plane over the hypercomplex number field of octonions[3]. The non-Arguesian property which makes it impossible to increase the number of dimensions[6] is a consequence of the non-associativity of octonions. In view of this we may expect the wave equation derived from $f(\chi, z, \psi)$ not to be self-adjoint, that is

$$(\chi H)\psi - \chi(H\psi) = k_0 \neq 0 \qquad (3)$$

which states that the probability of creation of matter is greater than that of anti-matter. This with k_0 cosmologically small (say $k_0/k = 10^{-40}$, $k = m_p c/h$) is the basic postulate of the new cosmology[7]. If we assume, as we must, that change is conserved this is the same as admitting the pair lepton-baryon as a new spin state. It is worth noting that several phenomenological theories[8,9] of interaction involve the subgroup G_2 of F_4 as gauge group and this may give a clue as to the fourth spin state.

Finally, non-associativity expresses something about the nature of observation which is not given by non-commutativity alone: namely, that pure states are unobservable. The idea that repeated observation should give certainty may seem essential to existing theory[10], but it is not difficult to see that it is the source of all the logical difficulties. What is involved here was known to C. S. Peirce[11] as the principle of triality and is this: observation requires not only an observer O and a universe U, but also signs S to pass between them. Now, while this situation is quite familiar in physics, there is the tacit assumption that the detachment of S from U leaves it unchanged. Just how near this is to being true is shown by the smallness of k_0/k: but when the existence of matter is in question the assumption is fatal. What is remarkable, however, is that when this triality is expressed in the variables (χ, z, ψ) there should exist the fundamental invariant form $f(\chi, z, \psi)$.

I thank the Leverhulme Foundation for the award of a fellowship (1949) during which this problem was investigated.

An Economical Prism System for Fast Spectrographs

FAST spectrographs for studying weak light sources, such as the airglow and the aurora, commonly use cameras of large aperture and short focal length—5 in. and 4 in. respectively in a typical case. A prism or grating sufficiently large to fill the aperture of the camera with light, and with sufficient angular dispersion to give a usable linear dispersion in the final spectrum in spite of the short focal length of the camera, necessarily has a high resolving power. On the other hand, the fastest available photographic emulsions are commonly used in these instruments, and spectra recorded on such emulsions show a resolving power only about one-twentieth of that given by the optical components. This large discrepancy led me to seek dispersing systems that would equal the usual systems in aperture and angular dispersion, but which would be less costly or have other advantages, though with resolving power sacrificed by up to a factor of ten.

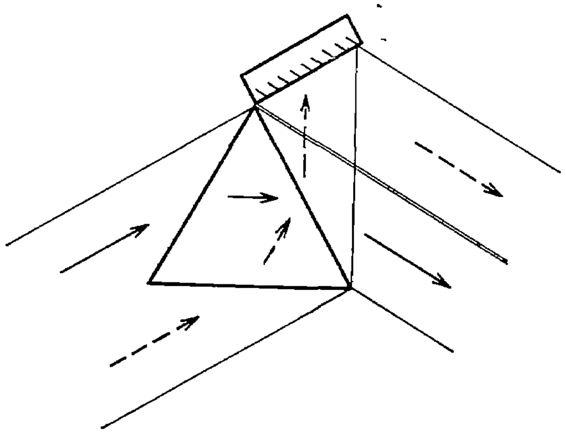

Fig. 1

I could not find a solution to my problem of cost reduction using diffraction gratings of types at present available. However, there are several advantageous prism systems. The most easily constructed is shown in Fig. 1. Half the light from the collimator is allowed to fall on the base of the prism, which becomes a second entrance face. The two angles of incidence must be equal. The second beam of light emerges in an unhelpful direction, but a plane mirror normal to the exit face redirects this beam parallel to the first, and the dispersions are then also in the same direction. The volume of glass in the prism of this economical system is only one-quarter that of the large simple prism which it replaces, since the height is unaltered but the widths of the faces are halved. For large prisms this means a reduction in cost of the raw glass by a factor considerably exceeding four. (It is true that there is now the extra cost and weight of an auxiliary mirror and its support, but there is still a considerable overall saving in both respects.) The reduced volume of glass also makes it easier to secure a piece free from striæ and other imperfections, and to achieve close temperature control in use.

At many wave-lengths the two emergent wave-fronts arrive at the camera in phase. (The two optical paths differ in length by a large whole number of wave-lengths.) The resolving power is then not significantly different from that given by the large simple prism. At those intermediate wave-lengths where the wave-fronts are out of phase the resolving power is reduced to a little less than half that given by the simple prism. These alternating wave-lengths are closely spaced through the spectrum. In a typical case for green light a change in wave-length of 0.01 Å produces the change from the in-phase to the out-of-phase condition.

Because the longer optical paths near the base of the large simple prism have been replaced here by short paths, the economical prism system is noticeably the more transparent at those wave-lengths where absorption is significant. A simple prism needs a face width nearly twice the face height if it is to deliver a beam of light of square or circular cross-section. To do the same, an economical prism requires faces that are square, or nearly so, and this reduces the difficulty of achieving a good optical figure on the faces. On the other hand, all three faces of the economical prism must have a good figure instead of only two. When the economical prism system is used, the prism is placed symmetrically on the axis of the collimator and the camera is much nearer to this axis than in the normal prism spectrograph. This leads to a less-inconvenient shape for the instrument and to greater compactness.

An economical prism system similar to that of Fig. 1 is in use in a spectrograph at the Dominion Physical Laboratory's Auroral Station at Lauder, Central Otago. It replaces an unsatisfactory diffraction grating which had a poor blaze and which was too small to fill the aperture of the camera with light. Exposure times for infra-red plates have been reduced by a factor of four. The prism is a liquid one filled with cinnamic aldehyde, chosen for its exceptionally high dispersion but having a high temperature coefficient of refractive index which demands control to ± 0·2° C. in our case.

METALLURGY

Point Defects in Niobium, Molybdenum and Tantalum

Experiments in which the thermal recovery of neutron irradiated and plastically deformed molybdenum[1-3] and tungsten[1,4-6] has been followed by measuring changes in electrical resistivity have revealed that in both metals one species of point defect, probably the lattice vacancy, becomes mobile above room temperature. The purpose of this communication is to give a preliminary account of similar experiments on neutron-irradiated niobium and molybdenum and plastically deformed niobium and tantalum.

Recrystallized niobium and molybdenum wires were irradiated for periods of 3, 6, 9 and 12 months at 40° C. in the reactor *BEPO* at the Atomic Energy Research Establishment, Harwell. The irradiations were carried out in a vertical hole in the reactor where the epithermal neutron flux was about $1{\cdot}2 \times 10^{12}$ n./cm.^{2}/sec.[1] and where about 1 epithermal neutron in 10 had an energy > 1 MeV. Isochronal and isothermal recovery curves were obtained for each metal and neutron dose. These revealed one recovery peak for each metal. That for niobium occurred at 120° C. and had an associated activation energy of 1·22 ± 0·02 eV. while that for molybdenum was at 160° C. and had an associated activation energy of 1·25 ± 0·08 eV. For both metals the magnitude of the recovery, $\Delta\rho$, passed through a maximum with increasing neutron dose. The temperature of the peak and the activation energy found for molybdenum agree closely with those reported earlier[1].

Recrystallized niobium and tantalum wires were deformed in tension at room temperature at a strain-rate of about $1{\cdot}3 \times 10^{-5}$ sec.$^{-1}$. Isochronal and isothermal recovery curves were obtained for specimens given elongations of up to 12 per cent for niobium and 16 per cent for tantalum. The niobium gave a recovery stage and an activation energy similar to those found for irradiated material. The relationship between the resistivity recovery, $\Delta\rho$, and the fractional tensile strain, ε, was found to be:

$$\Delta\rho = 0{\cdot}77\,\varepsilon^{1{\cdot}46}\,\mu\Omega\,.\,\text{cm.} \qquad (1)$$

Specimens with a higher initial dislocation density produced by annealing cold-drawn wire at 700° C., a temperature insufficient to cause recrystallization, behaved rather differently. The peak temperature and activation energy were the same but the relationship between $\Delta\rho$ and ε was found to be :

$$\rho\Delta = 0{\cdot}45\,\varepsilon^{0{\cdot}66}\,\mu\Omega\,.\,\text{cm.} \qquad (2)$$

In the case of tantalum a recovery peak was found at 120° C. with an associated activation of 1·25 ± 0·02 eV. The relationship between $\Delta\rho$ and ε was found to be:

$$\Delta\rho = 2{\cdot}01\,\varepsilon^{1{\cdot}41}\,\mu\Omega\,.\,\text{cm.} \qquad (3)$$

This work was supported financially by the United Kingdom Atomic Energy Authority and one of us (D. E. P.) is indebted to the Department of Scientific and Industrial Research for the award of a research studentship.

Aggregate Structure in Thin Nickel Films

It is recognized that in the initial stages of metal film growth by vacuum deposition the incident atoms may possess sufficient mobility on the substrate to form aggregates (clusters of crystallites)[1,2]. The degree of aggregation is chiefly a function of the substrate temperature and rate of deposition, and is conveniently thought of as a film thickness above which the films have a continuous structure. Various investigators have obtained electron microscopic evidence of the aggregated structure in thin films of a number of metals prepared under various conditions[3-6]. In addition, precise density measurements have indicated that aggregation in the initial portion of the film formation may result in a decrease in the observed density[7]. Severe aggregation may also be detected by electrical resistivity measurements. In contrast to the foregoing procedures, a simple chemical etching technique has been successfully used to observe metallographically the aggregate structure in thin nickel films. Despite the difference in magnification, such photomicrographs bear a striking resemblance to the published electron micrographs indicating aggregated structures in thin metal films.

The films used in this work were deposited on to glass substrates (40°–60° C.) in a vacuum of 2·8–10·0 × 10^{-6} torr at a rate of 8–14 Å./sec. The source consisted of nickel wire wound around three-braid tungsten wire filaments at a distance of 6–8 in. from the substrate, and arranged so that the vapour beam was at normal incidence to the substrate. Spectrographic analysis indicated a film purity of 99·9 per cent. X-ray diffraction examination indicated that the films had the normal face-centred cubic structure. Film thickness was determined by the use of multiple-beam interferometry.

The etching of the nickel films was accomplished by placing the films at normal incidence to the vapours of a heated (80° C.) solution of 50 per cent concentrated nitric : 50 per cent glacial acetic acid. The films were exposed for 3–5 sec., rinsed with water and examined metallographically; the procedure was repeated until a structure was evident. No apparent structure was noted until the film thickness was reduced to about 300–400 Å. Previous investigators using electron microscopy found no aggregation above about 300 Å. in nickel films prepared under similar conditions[5].

Representative photomicrographs of the various structures observed are shown in Figs. 1 and 2. It may be noted that in the thinner film (Fig. 1) the lateral size of the aggregates is smaller than in the thicker film (Fig. 2), which is to be expected. It is interesting to note the difference in the mode of etching in these films. In the thinner film the interior regions of the aggregates appear to have been preferentially attacked, while in the thicker film the boundaries are attacked. In this case, boundary refers to the material which is deposited in the channels between the aggregates already formed on the substrate.

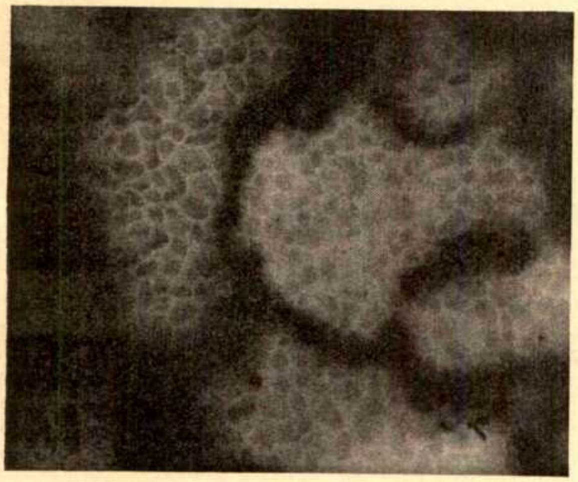

Fig. 1. Aggregate structure in thin nickel film approximately 100 Å. thick (original thickness, 1170 Å.). Wide dark channels indicate complete removal of film from substrate. (× 200)

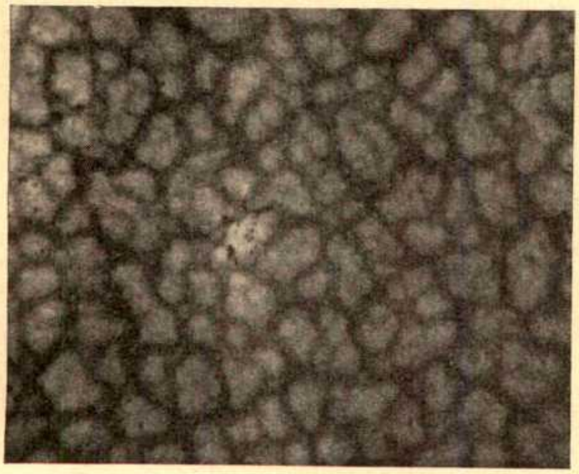

Fig. 2. Aggregate structure in thin nickel film approximately 300 Å. thick (original thickness, 1150 Å.) (× 200)

This chemical etching appears to be a fast convenient method to determine the gross structure of thin films so that adjustment of the deposition parameters may be carried out prior to examination of electrical, magnetic, optical or mechanical properties. Extension of this technique to other metals is under investigation.

ENGINEERING

Conducting Coatings for High-Voltage Insulator Stabilization

SINCE the pioneering work of Marshall and Forrest[1], many further attempts have been made to control the voltage distribution over the surface of ceramic insulators by incorporating a conducting system in the glaze layer to allow a small leakage current to flow through it; recent progress in this field has been reviewed in papers by Forrest *et al.*[2,3]. Lucas[4] and Smith[5], of this laboratory, have shown that the major disadvantage of the semiconducting compounds (commonly metal oxides) used to achieve the preferred value of resistivity, between 7 and 17 MΩ/sq., is their susceptibility to damage by electrolytic corrosion in polluted atmospheres. The purpose of this communication is to describe two new conducting coating systems which show some promise of possessing increased resistance to corrosion. They are glazes containing dispersions of carbon and glazes carrying a film deposited by vacuum evaporation of silicon carbide.

(1) Carbon powder of 99·5 per cent purity and mean particle size of 400 Å. was incorporated into a commercial feldspathic glaze normally used for covering high-tension insulators. When carbon/glaze mixtures were fired in dry nitrogen or argon, 50–75 per cent of the carbon was lost due to oxidation by the molten glaze. A glaze did not form if the mixture was fired in hydrogen. Experiments with firing atmospheres consisting of mixtures of nitrogen and hydrogen indicated that 5–20 per cent of hydrogen was necessary for the formation of a satisfactory glaze with few bubbles.

The glazes studied contained 1–10 per cent by weight of carbon. Surface resistivities ranging from 0·01 MΩ/sq. for 3 per cent carbon to 500 MΩ/sq. for 0·5 per cent carbon were measured, using fired-on silver contacts. Some spread of resistance values for a given composition was observed, typically 0·1–0·6 MΩ for 1·5 per cent carbon. Devitrification of the glaze has not been observed in thin sections cut from the glaze.

Electrolytic corrosion tests using the method described by Lucas[4] have been carried out on some specimens. Some electrolytic attack occurred, the carbon being removed, presumably as carbon dioxide. Carbon particles appeared in the electrolyte during the first hour of a test on one specimen which had a low resistance (0·08 MΩ). The particles were removed and the electrolyte changed; no more particles appeared during the remainder of the test. The damage observed in all the tests was slight, and there did not appear to be any increase in corrosion after the first few hours.

(2) Silicon carbide has been evaporated on to the surface of glazed and unglazed porcelain samples. This was carried out in vacuum, the pressure initially being 10^{-4} torr. An arc was struck between two rods of silicon carbide and maintained for about 15 sec., sufficient to give a film thickness of about 1μ. The porcelain pieces were heated by a molybdenum wire heating element to the temperatures given in Table 1. After removal from the vacuum deposition apparatus, silver contacts were fired on the film and the resistances measured at room temperature in vacuum (to avoid difficulties due to water vapour absorption). The surface resistivities are given in Table 1.

Table 1

Approximate substrate temperature	Glazed porcelain	Unglazed porcelain
20° C.	> 100 MΩ/sq.	> 100 MΩ/sq.
400° C.	1·1 ,,	5·3 ,,
800° C.	0·3 ,,	1·6 ,,
1,000° C.	41·0 ,,	27·8 ,,

Films that formed on the substrate at 20° C. were weak and easily removed from the surface. All the others were strong, coherent films which adhered well to the glaze and porcelain surfaces. The films had good resistance to abrasion and almost a mirror finish. The identification of the film material by X-ray and electron diffraction has proved difficult because of its thinness, but the evidence obtained so far is consistent with it being a mixture of silicon carbide, silicon and carbon with the possibility of other unknown constituents. The decomposition into silicon and carbon is in agreement with the observation of Drowart and de Maria[6] that these two species are formed when silicon carbide is vaporized. The minimum which appears to exist in the variation of resistance with deposition temperature should make control of resistivity simpler than with other systems. Electrolytic corrosion tests have been started and after 300 hr. there is no damage visible.

Work is continuing on both systems and corrosion-rates are being determined for comparison with figures reported for other conducting systems. The reproducibility of the resistivity values is also being examined.

We thank Mr. G. Siddall, of Edwards High Vacuum, Ltd., for the preparation of the silicon carbide films.

CHEMISTRY

Nitrogen-14 in Natural Diamonds

Kaiser and Bond[1] showed, by mass-spectrographic analysis, that many type I diamonds contain up to 0·2 per cent of nitrogen-14 as impurity, and quantitatively correlated this fact with certain features of the type I infra-red and ultra-violet spectra. Smith *et al.*[2] also found by electro-spin resonance measurements that there is a C—N bond in about one half of the diamonds examined. A correlation has now been established between spike intensity and ultra-violet transparency in natural diamonds[3], and dislocation loops and segregated platelets, presumed to be nitrogen, have been observed in etched diamonds by transmission electron microscopy[4]. Kaiser and Bond deduced that the nitrogen is substitutional and not interstitial, on the basis of density measurements on eight diamonds of gem quality.

Without a careful study of the other impurities normally present even in gem diamonds it seems doubtful whether density or lattice constant measurements (of the accuracy involved, which is better than 1 in 10,000) can prove much. Lonsdale[5] found a good type I diamond having a lattice constant smaller than any type II reported, including those of Kaiser and Bond; and fast neutron irradiation can reduce the diamond density by more than 4 per cent, so that small amounts of disorder, however produced, could easily account for the density changes found by Kaiser and Bond.

One most interesting question that seems so far to have excited no comment is that of the origin of the nitrogen, if and when it occurs. The suggestion that there is nitrogen at great depths in the Earth's crust is not favoured by most geological theory. It is important, therefore, to know whether the nitrogen might have diffused into the diamonds after they had been formed (in which case it might be expected to be interstitial).

It would be interesting, for example, to know whether a type II diamond could be converted into a type I by forcing nitrogen into it at high pressures. One might suppose that interstitial nitrogen could be driven off by heating *in vacuo*. If this nitrogen were responsible for the 'extra spikes', then these should disappear concurrently. This certainly does not happen. Rapid heating of type I diamonds to ~2,000° C., which produced fragmentation and incipient graphite formation, did not eliminate the extra spikes[6]. The extra spikes are also very strong in some graphite-coated diamonds from Premier Mine.

Examination of coated diamonds from the Belgian Congo showed that some core gave good extra spikes; the coat showed none. On heating pieces of core and coat simultaneously to 1,650° C., the coat graphitized, the core did not. These observations certainly imply that it is unlikely that nitrogen could have diffused into the diamond after crystallization. It seems most likely that if it is there at all, it was present as a substitutional impurity from an early stage of growth, and then or later segregated into platelets.

We have examined synthetic diamonds kindly given to us by Dr. R. H. Wentorf, jun., of the General Electric Research Laboratories, Schenectady, New York, which are expected, from their work in this field, to contain about 0·1–0·2 per cent of nitrogen. All synthetic diamonds when set near to Bragg positions show irregular diffraction spots and streaks which indicate imperfections, but these are distinguishable from the type I extra spikes, which are not present in these nitrogen-containing diamonds. This does not prove that the extra spikes found in natural diamonds cannot be due to nitrogen incorporated in some other way; but we regard it as significant that boron-containing synthetic diamonds do show evidence of extra spikes although these are not identical in appearance with those found for natural diamonds. If the extra spikes found for natural diamonds are due to the platelets observed by Evans, then the following questions still remain unanswered: (1) When, and how completely, did the impurity segregate into platelets? (2) If they do consist of nitrogen, and not some other impurity of mass number 14, where did the nitrogen come from?

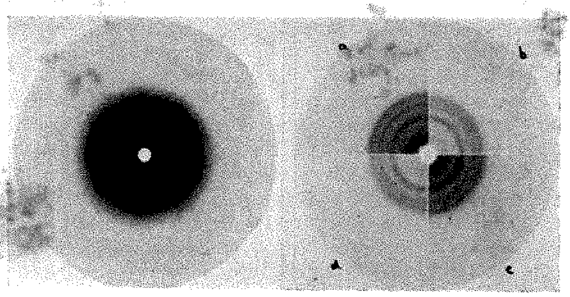
Liquid-induced Crystallization in Polymers

IT has been reported that a number of organic liquids will induce crystallization in amorphous polyethylene terephthalate[1]. This occurs readily at ambient temperatures, that is, at much lower temperatures than those at which the normal 'thermal' process is observed. It has been further suggested that the phenomenon of liquid-induced crystallization is probably common to other polymers which are crystallizable but which may be obtained in the amorphous state[2].

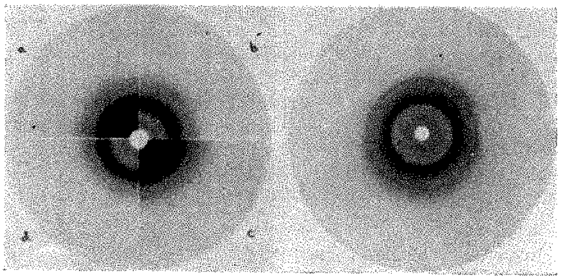
The presence of a crystalline phase has so far been inferred from a development of opacity, generally associated with a spherulitic structure in unoriented polymer, from a visual change in mechanical properties and from an increase in polymer density, due allowance being made for any imbibed liquid. This communication describes work which has been carried out to confirm this assumption by means of X-ray diffraction techniques and at the same time to extend the study to a bisphenol *A*-type polycarbonate.

A weighed sample of essentially amorphous polyethylene terephthalate film (approx. 1 × 1 × 0·025 cm.) was immersed for one day in acetone at 25° C. It was then removed and vacuum-dried at 60° C. for three days to remove most of the imbibed acetone, and re-weighed. A similar but unweighed sample was heated 30 min. in air at 180° C., that is, at a temperature at which normal crystallization proceeds rapidly. A third sample was left untreated. The X-ray diffraction photograph of the third sample is shown in Fig. 1*A*. In the case of the first and second samples, in order that their X-ray diffraction photographs could be readily compared a quadrant type cassette was used in conjunction with the flat plate camera (Fig. 1*B*).



A *B*

Fig. 1. X-ray diffraction photographs of polyethylene terephthalate. *A*, Untreated; *B*, *a* and *c*, heat-treated; *B*, *b* and *d*, acetone-treated



A *B*

Fig. 2. X-ray diffraction photographs of polycarbonate. *A*, *a* and *c*, untreated; *A*, *b* and *d*, heat-treated; *B*, acetone-treated

A similar procedure was carried out with samples of the polycarbonate which had been previously conditioned by heating rapidly to a molten condition at 360° C. and then plunged into 'dry-ice' in an attempt to freeze an amorphous state. The only difference in subsequent experimental procedure was in that one sample was heated at 200° C. instead of 180° C., that is, at a temperature approximately mid-way between the 'glass-temperature' and the melting-point[3,4] where for many crystallizable polymers the rate of crystallization is most rapid. In contradistinction to the acetone-treated sample no opacity was observed. Quadrant photographs of the quenched and heat-treated samples are shown in Fig. 2*A*. Fig. 2*B* shows the picture of the acetone-treated sample.

Density determinations were carried out by means of a flotation method[1], prior studies having indicated that, within the experimental time-scale, the method was also applicable to the polycarbonate. The results are given in Table 1.

Table 1

Polymer	Density (gm./c.c.) Untreated	Acetone-treated	Heat-treated
Polyethylene terephthalate	1·340	1·384	1·384
Polycarbonate	1·207	1·222	1·207

We conclude from these studies that crystallization has taken place in the polyethylene terephthalate, but reliable estimates of the crystalline-amorphous ratio were not attempted since the imbibed liquid is believed to interfere with the general X-ray scattering. From the position of the rings characteristic of crystalline material it appears that the acetone has no influence on the crystal structure, but some broadening suggests a smaller crystallite size in the case of the liquid-treated sample. It would be difficult to express an opinion, therefore, on the implication of the density results, that the degree of crystallinity is the same in both samples. It might be mentioned that the density values agree with that of previous workers[5]. In the case of the polycarbonate it appears that heat treatment has had little effect on the initial state, nor indeed does similar treatment at higher temperatures, but with acetone further crystallization is apparent. It is not easy to explain this behaviour. It may be that organic liquids (of the correct solubility parameter[1]) will induce crystallinity in those polymers which normally only crystallize with difficulty. It should be pointed out that the physical change and the development of opacity occur during immersion, thus repudiating any suggestion of a post-immersion and crystallization process.

We thank the Plastics Engineering Research Committee of this Institute for arranging facilities for part of this work, with the Department of Textile Industries.

A Phase Diagram for the Calcium Oxide–Carbon Dioxide System in the Eutectic Region

UNDER a pressure of carbon dioxide of 39·5 atmospheres, thermal dissociation of calcium carbonate takes place at 1,240°–1,242° C.[1,2] with the formation of a eutectic melt of lime and calcium carbonate. From determinations of the pressure–temperature relations below the eutectic point, and analyses of the melts formed by dissociation at pressures above the eutectic point, we have constructed a three-dimensional phase diagram for the system in the pressure-range 1–300 atmospheres (Fig. 1).

The surface *ABCD* represents the normal equilibrium between solid calcium carbonate and oxide below the eutectic point. Above the eutectic point, the system can best be considered in terms of two unidirectionally parallel surfaces *BHGC* and *BKMC*. The space behind the surfaces *ABCD* and *BHGC* can be regarded as the pressure–temperature region where solid calcium carbonate is stable, while the space above the surfaces *ABCD* and *BKMC* can be regarded as the pressure–temperature region where solid lime is stable. The region represented by the space between the surfaces *BHGC* and *BKMC* can only be bridged if melt formation takes place. Since the composition of any melt is determined by pressure and temperature, from the phase rule point of view, the all-liquid region will be represented by a surface (*ELF*). The lines *EF* and *EL*, formed by the intersections of the surfaces, consequently give the compositions of melts in equilibrium with the respective solid phases. In the diagram the composition scale refers solely to the compositions of the melts.

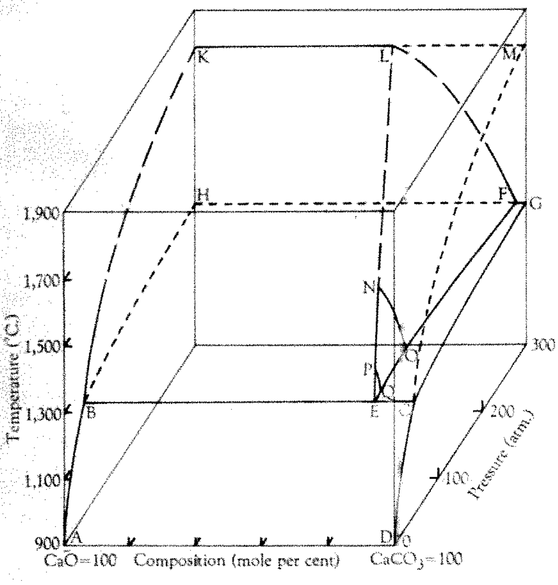

Fig. 1. Phase diagram for the eutectic region of the calcium oxide–carbon dioxide system

At the eutectic point, *E*, the composition is $CaCO_3$ 88·3 mole per cent, CaO 11·7 mole per cent. The melt in equilibrium with solid calcium carbonate at 300 atmospheres pressure and 1,308° C. (point *F*) contains 97 mole per cent of carbonate, and must therefore lie near the melting point of pure calcium carbonate. The latter is estimated to melt at about 1,325° C. at a pressure of 1,000 atmospheres or more; a conclusion supported to some extent by the work of Smyth and Adams[1].

The melt in equilibrium with solid lime at 100 atmospheres pressure of carbon dioxide and 1,457° C. (point *N*) contains 80 mole per cent of calcium carbonate. Experimental difficulties prevented determinations being made beyond this point, consequently the portion *NL* of the solid–liquid equilibrium line has been extrapolated in the direction of the melting point of lime.

The curved nature of the all-liquid surface was elucidated from analyses of melts with compositions lying on the isobars at 56 and 100 atmospheres in the all-liquid region (lines *PQ* and *NO* respectively).

It is to be expected that oxide–carbon dioxide systems in which melt formation occurs will in general be represented by phase diagrams similar to the above. The diagram for the strontium oxide–carbon dioxide system, for example, is very similar and differs only in the actual values of the parameters. Details of this system are to be published shortly.

We thank the Department of Scientific and Industrial Research for financing this work.

Methionine, the *N*-Terminal Amino-Acid of Phycoerythrins

THE phycoerythrins are photosynthetically active chromoproteins of algae[1]. We have performed *N*-terminal amino-acid analyses on spectrally different phycoerythrins from *Ceramium rubrum* (*R*-phycoerythrin, absorption maxima at 497, 542 and 568 mμ); from *Rhodochorton floridulum* (*B*-phycoerythrin, λ_{max} 544 and 566 mμ), and from *Phormidium persicinum* (*C*-phycoerythrin, λ_{max} 562 mμ). All three plants are marine algae, *Ceramium* and *Rhodochorton* being Rhodophyta, and *Phormidium* a member of the Cyanophyta.

Phycoerythrins were extracted from the algae into distilled water and were purified by precipitation with ammonium sulphate, dialysis against running water, chromatography (twice) on tricalcium phosphate-'Supercel' columns[2] and finally, except in the case of C-phycoerythrin, by crystallization from ammonium sulphate solution. Dinitrophenylation of the phycoerythrins was performed by Sanger's method[3].

Only one DNP-amino-acid was visible on paper chromatography of ether extracts of diluted hydrolysates of the DNP-phycoerythrins. The chromatograms were run on Whatman No. 1 paper and in a variety of solvent systems, including those described for DNP-amino-acids by Fraenkel-Conrat *et al.*[4]. Freshly prepared DNP-derivatives of the amino-acids which have been reported present in phycoerythrins were also chromatographed in these systems. Of these, only DNP-methionine behaved identically with the DNP-amino-acid from *R*-phycoerythrin in our six solvent systems. The identity of the two was confirmed by co-chromatography, and by alkaline hydrolysis of the DNP-derivatives[5]. The free amino-acid formed on hydrolysis was identified as methionine by paper chromatography in butanol/acetic acid/water (4 : 1 : 5), followed by development with ninhydrin. A small quantity of methionine sulphone, which was also present on the paper, was assumed to result from oxidation of methionine during hydrolysis. *R*-phycoerythrin, which had been oxidized with performic acid, yielded DNP-methionine sulphone after dinitrophenylation and hydrolysis; identification was by paper chromatography in four solvent systems with an authentic sample of DNP-methionine sulphone.

These results, which were not altered by further initial purification of the chromoprotein, show that methionine is the *N*-terminal amino-acid of *R*-phycoerythrin[6]. We have found by the same methods that methionine is also the *N*-terminal residue of *B*- and of *C*-phycoerythrins.

We thank L. Provasoli for the *Phormidium* culture and Miss Dani Curley for growing the alga and purifying its phycoerythrin. This investigation was supported by the U.S. Air Force through its European Office (contract No. *AF* 61 (052)–409).

Chromatography of Some Phenolic Amines

LITTLE work has, as yet, been published dealing with the paper chromatography of urinary phenolic amines. Solvent systems used have been isopropanol–ammonia[1] and *n*-butanol–ammonia or –methylamine[2,3] for the first direction, followed by *n*-butanol–acetic acid[1–3]. Such systems, however, give poor resolutions, particularly in the group of amines derived from phenylethylamine, and have little potential use except for revealing grossly abnormal excretions of the few compounds that can be unambiguously identified: probably the demonstration of increased excretion of metanephrine and normetanephrine in phæochromocytoma[3] or stress represents the limit of their usefulness.

Further investigations in these laboratories indicate that the general separation of phenolic amines thus far identified in human urine (Table 1) from each other and from other diazo-reacting amines requires the use of *tert.*-amyl alcohol/17 per cent aqueous methylamine (4 : 1) (solvent *A*) in the first direction; on Whatman paper No. 1 a 10-in. overnight ascending run must be carried out at about 32° C. Two solvent systems have been found to be particularly suitable for development in the second direction at about 21°. The first of these, solvent *B*, is an example of the type *sec.*-butanol/aqueous pyridine buffer (4 : 1); the buffer solution, *p*H 4, has the composition water 100 : pyridine 10, acetic acid 41 by volume. The second, solvent *C*, has the composition nitroethane/70 per cent aqueous acetic acid (9 : 4). For 10-in. ascending runs about 16 hr. (*B*) and 3 hr. (*C*) are required. Approximate distances travelled by authentic amines under the conditions outlined above are indicated in Table 1.

Table 1. MOBILITIES OF AMINES IN SOLVENTS *A*, *B* AND *C*

Amine	*A*	*B*	*C*
Tyramine (ref. 1)	166	100	121
m-Tyramine (ref. 1)	150	103	131
o-Tyramine (ref. 1)	191	125	153
3-Methoxytyramine (refs. 2 and 3)	130	73	152
p-Octopamine (refs. 2 and 4)	69	70	70
p-Sympatol (refs. 2 and 4)	116	83	124
Normetanephrine (refs. 1, 2 and 3)	51	41	89
Metanephrine (refs. 1, 2 and 3)	96	64	145
N-Methylmetanephrine (ref. 3)	142	61	188

Figures indicate typical distances run (mm.) measured to centre of spot. For composition of solvents and approximate conditions, see text. Amines applied to paper as hydrochlorides, except *p*-sympatol (tartrate).

Both the combinations *A*–*B* and *A*–*C* have been applied to the two-dimensional chromatography of urine extracts. Some anomalies have been noted: thus *m*-tyramine may give rise to multiple spots; absolute and relative movements, particularly in *C*, are somewhat different from the values recorded in Table 1; extensive decomposition of the 4-hydroxy-3-methoxyphenyl amines in *C* has been observed on occasion. Any disadvantages appear, however, to be small by comparison with the enormously improved resolutions effected. For example, one of a group of very similar compounds, previously provisionally identified as *p*-sympatol[2], proved almost impossible to identify with certainty in any given urine. It now seems probable that it may be isolated as a single spot using the *A*–*C* combination and that other systems used fail to reveal the presence of a contaminating compound which is rather commonly present in urine extracts and which may sometimes be the major constituent of a single mixed spot. This substance shows no evidence of being an artefact from *p*-sympatol and has an R_F value slightly less than has that amine in *A* and distinctly less so in *C*. Other spots which could have been confused with *p*-sympatol have been observed less frequently and are completely separated from it in either of the systems *A*–*B* or *A*–*C*.

BIOPHYSICS

Mechanical Damage of Keratin Proteins observed by Electron Spin Resonance

It has been shown by electron spin resonance that mechanical damage to biological material causes the formation of free radicals and changes of chemical valence. The change of hæmoglobin to methæmoglobin and the appearance of an unidentified free radical have been observed, and were due to mechanical damage of whole blood by freeze drying[1]. Mechanically excited electron spin resonance spectra of synthetic organic polymers were studied by Bresler *et al.*[2].

In the experiments with mechanically damaged keratin carried out in this laboratory, intense electron spin resonance spectra were obtained. Most experiments were performed with hoof keratin, but other keratinous substances, such as finger nails, feather, etc., have similar spectra. The material was filed with a rough file, in atmospheres of both air and nitrogen with 7 per cent oxygen.

The powder was inserted into the cavity of a standard spectrometer operating at 9 kMc./s. and with 100 kc./s. magnetic modulation, in open or closed sample tubes, at room temperature. Fig. 1 shows the spectra obtained by filing the hoof in air and their change with time; Fig. 2 is a recording of the spectrum from the material treated in nitrogen.

The spectra are very similar to those of X-irradiated keratin proteins[3-5], but show greater intensity and are better resolved. Just as with X-irradiated keratin, they can be assigned to the presence of amino-acids containing sulphur.

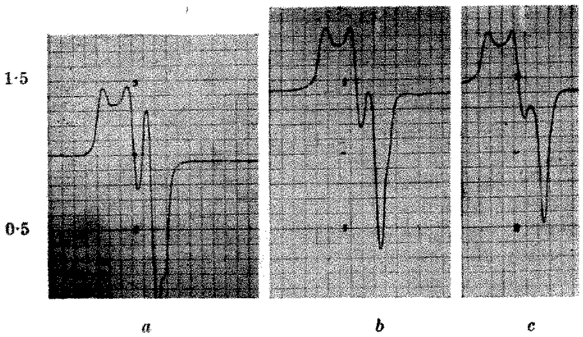

Fig. 1. Electron spin resonance spectra of hoof proteins excited by filing in air. (*a*) Fresh powder; (*b*) after 4 min.; (*c*) after 10 min.

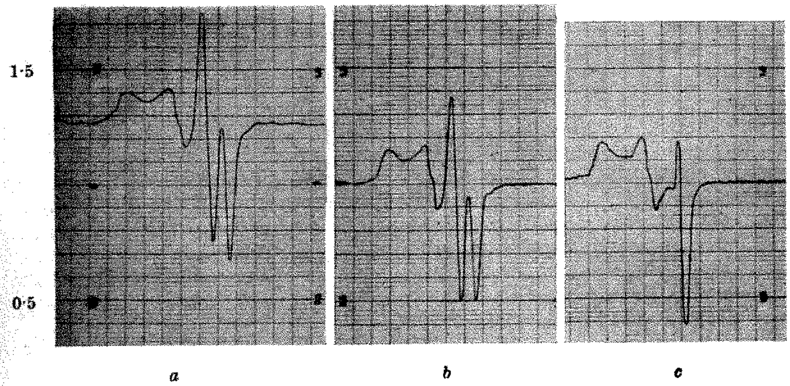

Fig. 2. Electron spin resonance spectra of hoof proteins excited by filing and measuring the samples in nitrogen. (*a*) Fresh powder; (*b*) after 80 min.; (*c*) after 3 days

The spectra obtained in air (Fig. 1) closely resemble those of cysteine and cystine[3-5], and the spectra observed in nitrogen are similar to those of glutathione, observed by Henriksen and Pihl[6]. It may be noted that McCormick and Gordy[4] found no distinct difference between the spectra of cystine, cysteine and reduced glutathione, while oxidized glutathione was not clearly resolved.

Due to the ease with which mechanical excitation of the electron spin resonance spectra is brought about, it is probable that many effects in the spectra of biological objects, which have been thought previously to be of metabolic origin, are artefacts caused by mechanical damage during the treatment of the samples. This is true especially in the case of substances containing electron sinks[7].

The effects observed may be of importance in connexion with the processes of wounding and healing, for the initiation of cancer by mechanical stimulation etc.

Generation Time of Epithelial Cells in the Human Colon

The duration of the mitotic cycle in intestinal epithelial cells of rodents has been measured by radioautography after tritiated thymidine[1,2]. Proliferating jejunal and colonic epithelial cells in rodents have total generation times of about 18 hr., DNA synthesis (*S* phase) times of 5–8 hr., and pre-mitosis (G_2) and mitosis times of 1·5–2 hr. In man, investigations of mitotic indices and autoradiographic studies with tritiated thymidine have suggested turnover times of intestinal epithelial cells of several days[3].

This investigation gives measurements of the component parts of the mitotic cycle of human intestinal epithelial cells after tritiated thymidine and the effect of 5-fluorouracil on the proliferative cycle. Two patients having a colostomy opening with normal mucosa of the transverse colon attached to the anterior abdominal wall after resection of carcinoma of the rectum were examined; both had liver metastases. The first was given intravenously 0·057 μc./gm. of tritiated thymidine, the second 0·26 μc./gm. (specific activity 6·59 curies/mM dissolved in 10 ml. of water). Three months later the second patient was treated with 5-fluorouracil, total dose 105 mgm./kgm., for 16 days. At the onset of toxicity, the drug was discontinued and a second tritiated thymidine injection given. After each injection, serial biopsies of colonic mucosa were taken from the colostomy opening from the surface to a distance of 2 in. below. Tissue specimens were fixed in neutral formol-saline, embedded in paraffin, and sectioned at 5μ. For radioautography, slides were dipped in *NTB* (Kodak) liquid emulsion, exposed for 2–3 months, developed and stained with hæmatoxylin and eosin. The fraction of labelled mitoses in colonic crypts, as well as the rate of duplication of labelled cells, were determined.

Fig. 1 shows the fraction of labelled mitoses at various times after tritiated thymidine in the first patient. Each circle represents results from 2–4 biopsy specimens taken at the same time. The number of mitoses at each point range from 7 to 58 with a mean of 27·4. The vertical bars delineate the 95 per cent confidence limits. Although many labelled cells are seen at 15 min., almost no labelled mitoses are present. This represents the minimum for the premitotic (G_2) phase of the generation cycle.

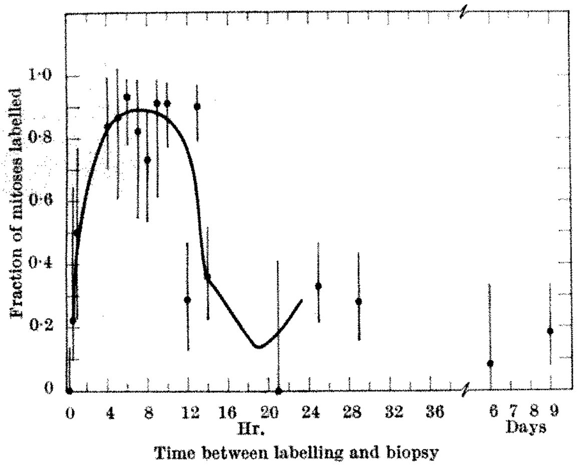

Fig. 1. Fraction of mitoses labelled at various intervals after injection of tritiated thymidine in subject 1. Each symbol represents pooled data from 2–4 biopsy specimens. The vertical lines define 95 per cent confidence intervals

The earliest part of the ascending wave of labelled mitoses records those mitoses derived from cells leaving DNA synthesis (*S* phase) at the time of injection. The descending part of the wave represents labelled mitoses derived from cells entering *S* phase at the time of injection. After 1 hr., 50 per cent of mitoses were labelled (Fig. 1). This is approximately the mean duration of G_2 plus about half the mitosis time[1]. The fraction of mitoses labelled rose rapidly to about 0·92. The midpoint of the subsequent decline of the wave of labelled mitoses was about 12–15 hr. The mean duration of the *S* phase is measured by the distance between the midpoints of the rise and fall of the wave of labelled mitoses; this is about 11–14 hr. Labelled mitoses are lowest at 14–24 hr. This trough represents cells in post-mitosis (G_1), mitosis, and pre-mitosis (G_2) phases respectively at the time of injection; these were therefore not labelled. Since G_2 is known to be short, the distal part of the trough can be used to provide a minimum estimate of the total generation time—about one day. Subtraction of 15 hr. for the *S*, G_2 and mitosis phases gives an estimated 10 hours or longer for the G_1 phase. Counts of labelled cells at 30 min. and 24 hr. show a corresponding rise in numbers of labelled cells from a mean of 14·5 ± 1·4 (*S.E.*) to 31·0 ± 1·6 (*S.E.*), and an obvious reduction in the number of grains per cell at 12 hr. and later.

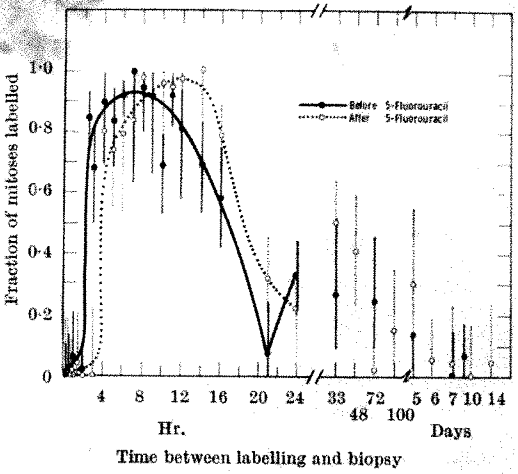

Fig. 2. Fraction of mitoses labelled at various intervals after injection of tritiated thymidine in subject 2. Solid line drawn through values obtained before and dotted line after administration of 5-fluorouracil

Fig. 2 shows the fraction of mitoses labelled at various times after tritiated thymidine in the second patient. The solid line records values before, and the dotted line after, 5-fluorouracil. The number of mitoses at each point was 8–93 with a mean of 37·2. In the control measurements, practically all mitoses were unlabelled until 2 hr. after thymidine. This is the minimum time of G_2 in Subject 2. The wave of labelled mitoses reached a peak at about 6–8 hr. The wave of labelled mitoses then declined; the distance between the midpoints of rise and fall, *S* phase, is close to 15 hr. The duration of the entire generation cycle from these measurements is also about one day.

After 5-fluorouracil, there were abnormalities in the mucosal epithelial cells; nuclei were large, stained lightly, and there were irregularities in chromatin pattern. One day after stopping 5-fluorouracil these abnormalities disappeared. There was a delay in the onset of labelled mitoses, the G_2 duration being increased to about 4 hr. The wave of labelled mitoses was also shifted to the right after 5-fluorouracil. The *S* phase—about 13–17 hr.—was unchanged. The *S* phase might have been prolonged if the drug had not been stopped at the time of injection of thymidine.

Human specimens were also examined two weeks after thymidine. At this time one would expect most labelled cells to have been removed from the mucosa. In previous investigations with animals, proliferating crypt cells divided rapidly and diluted their label to background-level within several days. Other heavily labelled cells migrate to the surface of the crypts and are extruded into the lumen. Labelled cells therefore rapidly disappear from the mucosa. However, in the colonic mucosa of several species, a few epithelial cells do not follow the pattern of proliferation and migration described for most cells; a few heavily labelled cells are retained in the mucosa for prolonged periods[2,4]. Prolonged retention of heavily labelled epithelial cells is more marked in distal colon than in duodenum or jejunum of other species[5]. In man, although there was rapid dilution of label and removal of most heavily labelled cells two weeks after injection of tritiated thymidine, a few heavily labelled epithelial cells persisted in colonic crypts, indicating prolonged retention.

We thank Drs. H. Quastler and L. D. Hamilton for their review of this work, and Dr. B. Clarkson for assistance in selection of patients. This work was aided by U.S. Public Health Service grants *A*-3165

and *C*–3697 and the John A. Hartford Foundation, Inc.

BIOCHEMISTRY

Electron Microscope Examination of some Globular Proteins

A MODEL of a protein molecule should be compatible with all experimental evidence available, it should explain changes of these properties corresponding to various experimental conditions, and give a feasible concept of its synthesis in the cell. From these criteria, Segal, Dornberger and Kalaidjiev have proposed a model for globular proteins: the "Faltentrommel"[1].

According to this hypothesis the protein should contain a cylindrical hole, coaxial with the outer limiting cylinder. This hole should be large enough to be seen in the electron microscope. Proteins have been examined by various authors in the electron microscope, but to our knowledge no holes have so far been found (for example, refs. 2–5). For our experiments we have used albumins (ovalbumin and bovine serum albumin (our own preparations) as well as bovine serum albumin from Sera, Heidelberg, and ovalbumin from Kebo, Stockholm) dissolved in distilled water (1 mgm./l.). A small drop of the solution was deposited on the specimen grid and allowed to dry. Some of the grids were examined directly, some were covered by a very thin layer of carbon, some were shadowed (platinum at an angle of 20°), and some were stained with osmium tetroxide. Pictures were usually taken at an instrumental magnification of 20,000, and at a voltage of 48 kV. Selected parts of the electronmicrographs were enlarged photographically (× 30, Figs. 1–4).

The electron microscope does not permit very accurate measurement of the particle-size of proteins[2], but our values are in agreement with results published by other authors. At very high magnifications some particles are represented as rings in the electronmicrographs (Figs. 1–4). They are sometimes particularly noticeable in agglomerations (Fig. 4). Osmium-stained particles show more contrast than unstained ones, if photographs have been taken under the same conditions. The results of a qualitative evaluation of osmium staining will be reported later.

An inspection of blank collodion films shows that these rings are not structures of the supporting film and that they have not been introduced by the solvent. By careful focusing also artefacts have been avoided which may be introduced by the formation of Fresnel rings. According to its position on the supporting film a hollow cylinder will give a picture of either roughly uniform or roughly annular density distribution. Thus from the electron microscopic evidence we may draw the conclusion that the proteins which we have examined have roughly the shape of hollow cylinders, as postulated by the hypothesis of Segal, Dornberger and Kalaidjiev. They have apparently a tendency to 'tumble over', as annular structures are not too frequently found. Sometimes, if they are more closely packed they seem to support each other, and a greater number of annular structures is observed (Fig. 4).

We think there are a few reasons why these annular structures have not been observed before. They are not too frequent, and they can only be detected at very high magnifications. Shadowing makes their detection more difficult, though they are often indicated by a blob of metal. Furthermore, the contrast in unshadowed specimens is very poor, and it may have been enhanced by working at a very low voltage, as we did. Finally, we would like to mention that one of us[6] found annular structures in the protein-containing sub-units of the chromatoid body of *Entamoeba invadens*, and that also X-ray findings

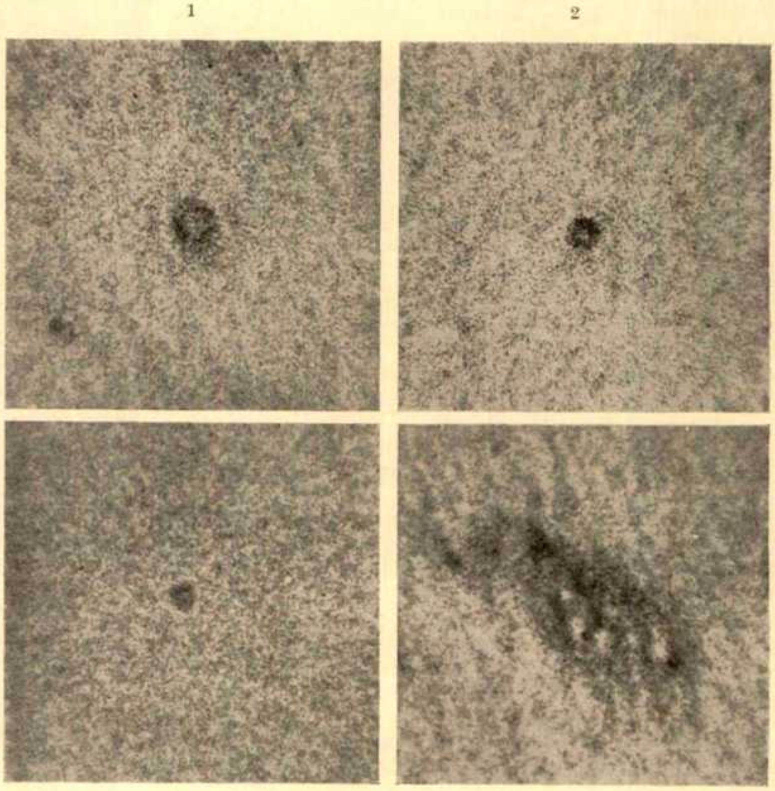

Fig. 1. 1 mol. of serum albumin, osmium stained (30,000); Fig. 2, 1 mol. of serum albumin, untreated (20,000); Fig. 3, 1 mol. of ovalbumin, untreated (20,000); Fig. 4, agglomeration of molecules of serum albumin, osmium stained (30,000). (All photographs enlarged × 30)

indicate the existence of a hole in the molecule of a globular protein[7].

Separation of Catecholamines by Paper Chromatography

One of the difficulties encountered in investigating the metabolism and distribution of catecholamines has been the inadequate separation and isolation of these substances from tissue extracts[1]. Various solvent systems have been used for developing chromatograms of the catecholamines[2-4]; but none has effected a complete separation. The method described here involves a novel technique of 180° solvent-reversal paper chromatography utilizing two different solvent systems, which makes possible separation of 3,4-dihydroxyphenylalanine (dopa), 3-hydroxytyramine (dopamine), norepinephrine, epinephrine, and 3,4-dihydroxyphenylacetic acid, on a single paper strip.

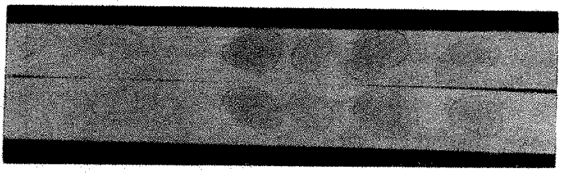

Fig. 1. Separation of catecholamines. From left to right: 3,4-dihydroxyphenylacetic acid; 3,4-dihydroxyphenylalanine; norepinephrine; 3-hydroxytyramine; epinephrine

Approximately 25 μgm. of each of five catecholamines, dissolved in 1 per cent hydrochloric acid in 95 per cent ethanol[5], were spotted 7 cm. from the end of a strip or sheet of Whatman No. 1 filter paper, 57 cm. in length. The papers were developed by the descending technique for 28 hr. with an 88 per cent aqueous solution of phenol in an atmosphere of 1 *N* hydrochloric acid. The chromatograms were washed with benzene to remove the phenol and allowed to dry completely. The papers were then redeveloped with *n*-butanol saturated with 1 *N* hydrochloric acid[3], again by the descending technique for 25 hr. However, the second solvent was run in a direction opposite (180°) to the phenol. After drying completely, the spots were developed by spraying with 0·44 per cent potassium ferricyanide solution in phosphate buffer *p*H 7·8 (ref. 2). When the colours did not appear immediately, the papers were exposed to ammonia vapour to enhance their colour development. For further identification of the spots, the papers were viewed under ultra-violet light (Table 1).

The R_F values for the individual catecholamines developed with each solvent system separately are indicated in Table 1. To separate the catecholamines, the two solvent systems were run in an opposite direction, therefore a net *R* value (*Re*; based on epinephrine) was calculated for each compound. Epinephrine was considered arbitrarily to represent the solvent front and was given a value of 1·0 based on the starting line of the first solvent system. Generally, two compounds will be separated if the difference between their net *Re* values is greater than 0·1. Chromatographic separation of radioactive catecholamines in tissue extracts was improved by addition of 20–40 μgm. of each of the corresponding carriers to the extract before application to the paper.

Table 1. Staining Characteristics and R_F Values of Catecholamines

Compound	Colour with potassium ferricyanide	Colour under ultra-violet light	R_F in phenol	R_F in butanol	Net *Re** value phenol and butanol
3,4-Dihydroxyphenylacetic acid	faint purple	purple	0·61	0·85	0·17
3,4-Dihydroxyphenylalanine (dopa)	purple	dark purple	0·26	0·30	0·50
Norepinephrine	pink-purple	yellow	0·30	0·22	0·63
3-Hydroxytyramine (dopamine)	purple	dark purple	0·48	0·31	0·78
Epinephrine	pink-mauve	yellow	0·54	0·25	1·00

* *Re*, net *R* values based on epinephrine which was considered arbitrarily to represent the solvent front and was given a value of 1·0.

Oxygen Consumption, Lactic Acid Production and Protein Synthesis of Peritoneal Macrophages

It has been shown that macrophages, obtained by injection of paraffin oil into the peritoneum of the rabbit, are facultative anaerobic cells[1]. In order to evaluate the ability of respiration and glycolysis to supply energy for biosyntheses in these cells, the incorporation-rate of a labelled amino-acid into protein, as a model of a synthetic process, was investigated in aerobic and anaerobic conditions[2,3]. At the same time, consumption of oxygen and production of lactic acid were also measured.

Table 1. Lactic Acid Production by Peritoneal Macrophages

	No. of experiments	μmoles/mgm./N/hr. (1)	μmoles/10^6 cells/hr. (2)
Aerobiosis	7	4·9 ± 1·17	0·09 ± 0·021
Anaerobiosis	10	8·2 ± 1·09	0·15 ± 0·019

Incubation mixture (final concentration): NaCl, 108 m.moles; KCl, 4·7 m.moles; $CaCl_2$, 1·3 m.moles; $MgSO_4$, 1·2 m.moles; sodium phosphate buffer, 5·0 m.moles; sodium bicarbonate, 25·0 m.moles; glucose, 15 m.moles. Incubation lasted 60 min. at 38° C. in a metabolic shaking incubator. The reaction was stopped adding 10 per cent trichloroacetic acid and lactic acid was estimated by the method of Barker and Summerson (ref. 8). Gas phase: 95 per cent oxygen + 5 per cent carbon dioxide; 95 per cent nitrogen + 5 per cent carbon dioxide. Figures are means ± *S.E.*

(1) Nitrogen estimated by the Nessler method (ref. 9).

(2) Cell counts made in a Thoma–Zeiss hæmocytometer.

Table 2. OXYGEN CONSUMPTION BY PERITONEAL MACROPHAGES

	No. of experiments	μmoles/mgm. N/hr. (1)	μmoles/10⁶ cells/hr. (2)	QO_2	No. of experiments
Endogenous	24	2·96 ± 0·118	0·053 ± 0·0021	6·4	7
Succinate	17	2·78 ± 0·124	0·050 ± 0·0022	6·5	8
Glucose	17	2·64 ± 0·169	0·047 ± 0·0030	5·1	4

Incubation mixture (final concentration): NaCl, 127 m.moles; KCl, 5·1 m.moles; $CaCl_2$, 2·7 m.moles; $MgSO_4$, 1·3 m.moles; sodium phosphate buffer (*p*H 7·4), 10·3 m.moles. When added, succinate and glucose were, respectively, 10 m.moles and 15 m.moles. The incubation was carried out in a Warburg apparatus at 38° C. for 60 min. Readings were taken every 10 min. Gas phase: air. 30 per cent potassium hydroxide in the central well. Figures are means ± *S.E.*

(1) and (2), same legends as in Table 1.

10 ml. of sterile saline containing 0·1 mgm. glycogen[4] were injected intraperitoneally in each rat used throughout these experiments. Seven days later, the rats were killed (10–15 rats for each experiment) and the peritoneal cavity rinsed with Ringer-phosphate in order to collect the cells; the suspensions were pooled and then centrifuged at 150*g*. The precipitate was resuspended in the incubation mixtures as shown in Tables 1 and 2. Mononuclear cells (macrophages) accounted for 85 per cent of the whole picture as microscopically checked; other cells were small lymphocytes, eosinophils and mast-cells. Glycogen was used because of its strong chemotactic property on migrating cells[5] and because it eliminates a possible metabolic impairment caused by paraffin oil.

Aerobic and anaerobic lactic acid production, oxygen consumption, either endogenous or with sodium succinate and with glucose as substrates, and leucine-1-C^{14} incorporation-rate into protein were measured.

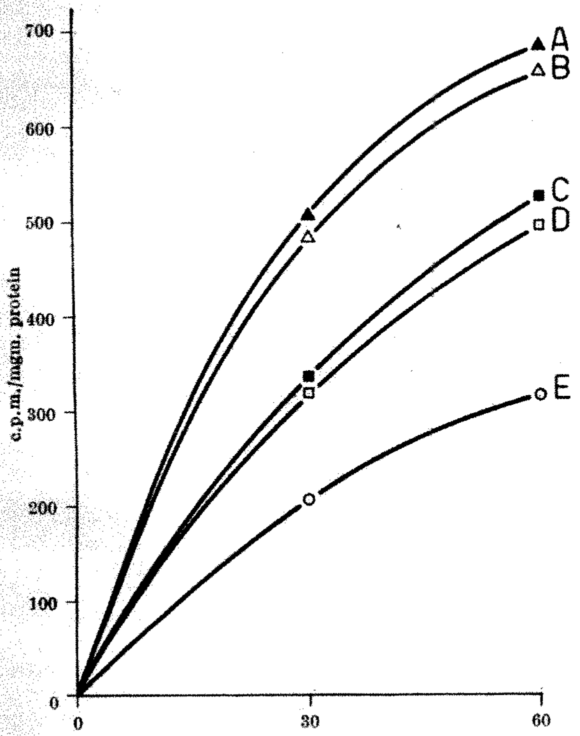

Fig. 1. Incorporation of DL-leucine-1-^{14}C into protein by peritoneal macrophages. Incubation mixtures were the same as in Tables 1 and 2: 0·526 μmole (4 μc.) leucine added. Incubation lasted 30 and 60 min. at 38° C. Cell proteins were purified (ref. 10), weighed, suspended in absolute ethanol and plated as infinitely thin samples. Radioactivity was measured with a mica-window Geiger–Müller counter. Counting error was less than 3 per cent. *A*, Incorporation in phosphate medium, glucose added, air phase; *B*, incorporation in bicarbonate medium, glucose added, 95 per cent oxygen + 5 per cent carbon dioxide phase; *C*, incorporation in phosphate medium, no substrates, air phase; *D*, incorporation in phosphate medium, succinate added, air phase; *E*, incorporation in bicarbonate medium, glucose added, 95 per cent nitrogen + 5 per cent carbon dioxide phase

Results are summarized in Tables 1 and 2 and in Fig. 1. It is evident that macrophages produce lactic acid under aerobic conditions. The values are nearly a half of those produced anaerobically. In both cases the lactic acid produced is less than that observed by Harris and Barclay[1]. Addition of glucose to the incubation medium depresses oxygen consumption (in some experiments inhibition was more than 30 per cent), suggesting the presence of a Crabtree effect in these cells[6]. Succinate, on the other hand, does not stimulate the respiratory activity. In spite of the Crabtree effect, top values of incorporation of amino-acid were attained in aerobic conditions with glucose as substrate; the incorporation-rate with succinate as substrate was lower than before and was not statistically different from that observed in absence of any substrate. Least incorporation-rates were reached in anaerobic conditions.

These results show that glucose in aerobic conditions stimulates protein synthesis despite its inhibitory effect on consumption of oxygen; on the other hand, succinate fosters neither endogenous respiration nor incorporation of amino-acid into protein. This may suggest that glucose stimulates protein synthesis in conditions in which the supply of oxidative energy is reduced.

A similar behaviour was reported by Ciaranfi and Fonnesu for Yoshida hepatoma-ascites cells[7]. Experiments with specific inhibitors of oxidative and glycolytic pathways are in progress to clarify this problem.

Immunoelectrophoresis of Bovine Growth Hormone

As part of my investigations on the production of growth hormone in the embryo, I have performed immunoelectrophoresis on bovine growth hormone.

Recently, Ferguson and Wallace[1] reported that starch-gel electrophoresis revealed two components in bovine growth hormone preparations with approximately equal biological activity. My findings seem to support their results.

Rabbits were injected subcutaneously with 5 mgm. highly purified bovine growth hormone (Organon) in 1 ml. of physiological saline, mixed with an equal volume of Freund's adjuvant complete (Difco). This was followed by weekly injections of 2 mgm. suspended in the same mixture. The animals were bled at intervals and antibody titres were determined with a micro precipitin interfacial ring test[2]. Injections were continued until a titre of at least 1 : 12,800 (antigen dilution) was reached, usually after 6–8 weeks.

In most cases a total dose of about 20 mgm. bovine growth hormone was quite sufficient to obtain this titre, contrary to the findings of Hayashida and Li[3], who needed 80 mgm., using a different immunization method.

Electrophoresis was performed after the method of Wieme[4], which gives a separation in very sharp bands. It was carried out for 45 min. with a 0·5 or 1 per cent solution of bovine growth hormone on microscopic slides (76 mm. × 26 mm.) covered with 2 ml. of gel (1·5 per cent Difco 'Special Agar Noble' in barbiturate buffer, *p*H 8·6, 0·05μ). With 130 V. applied across the electrodes, the amperage was 3–4 m.amp.

Antiserum was applied as usual, and the reactions were read after 24 and 48 hr.

In all cases one single precipitation line was observed, either a long asymmetrical line (Fig. 1*A*) or a two-peaked line (Fig. 1*B*). This indicates the presence of substances with different electrophoretic mobilities, but with the same antigenic properties.

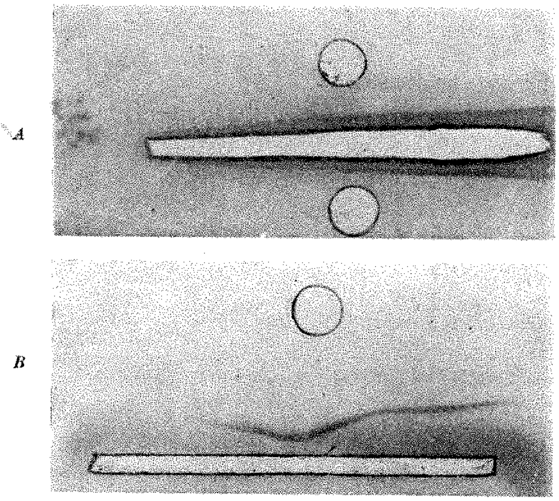

Fig. 1. Immunoelectrophoretic pattern after staining with amido-black. *A*, Antiserum 1 against bovine growth hormone, 0·5 per cent (upper basin) and 1 per cent (lower basin); *B*, antiserum 2 against bovine growth hormone, 1 per cent

Some of the antisera also reacted with bovine serum proteins: precipitation lines, different from those with bovine growth hormone, were seen with albumin and with γ-globulin.

As these lines were not found with the bovine growth hormone itself, the amount of serum proteins contaminating the hormone samples must have been very small, although sufficient to evoke antibody formation.

The aspecific antibodies could be removed by absorption, and the reaction with bovine growth hormone remained the same after this procedure.

My findings can be explained most easily by the existence of electrophoretically different forms of growth hormone. As the same line was observed with saline extracts of single bovine pituitaries, put up against the absorbed antiserum, the possibilities of degradation of the hormone during the isolation process or of polymorphism seem to be excluded.

It is interesting to note that Hirschfeld, Gemzell and Wide[5] found the same pattern of lines with immunoelectrophoresis of human growth hormone as I obtained with the bovine preparation, while Ferguson and Wallace[1,6] reported a very different behaviour of human and bovine growth hormone in starch-gel electrophoresis.

I thank Dr. J. D. H. Homan (Organon, Oss, Holland) for gifts of bovine growth hormone. Part of this investigation was made possible by a grant from the Dutch Ministry of Education, Arts and Sciences (1959–80.004).

Dialysable Neuraminic Acid in Human Cerebrospinal Fluid

Because of the presence of interfering sugars in great excess, it has not been possible heretofore to determine with any certainty in other laboratories as well as our own[1] whether neuraminic acid occurs in dialysable form in cerebrospinal fluid. Recent methods developed in this laboratory for the quantitative fractionation of all the carbohydrate constituents of specimens of human cerebrospinal fluid have been described in the first paper of this series on the cerebrospinal fluid[2]. By using concentration by lyophilization and exhaustive dialysis, all the solids of cerebral spinal fluid have been separated quantitatively into non-dialysable and dialysable fractions. An accurate estimate of the neuraminic acid bound to protein has thereby been obtained without interference from dialysable sugars[2,3]. Evidence is now presented that neuraminic acid does indeed occur in dialysable form as well as in protein-bound form in specimens of human cerebrospinal fluid. The dialysable neuraminic acid does not, however, appear to be free, but rather to be bound to hexose and nitrogenous residues in glycopeptide-like low molecular weight compounds.

The methods used for the fractionation of whole cerebrospinal fluid are as outlined in the previous communication[2]. Neuraminic acid was determined by means of the thiobarbituric acid method[4]. Neuraminic acid was separated from the other constituents in the dialysable fraction of cerebrospinal fluid by means of a 3-column system in series consisting of 'Amberlite *IR*–120', 'Dowex 3–*OH*', and 'Dowex 1-formate'. 'Amberlite *IR*–120' was used to remove sodium ions. 'Dowex 3–*OH*', used to remove chloride ions, was shown to allow free neuraminic acid to pass through unadsorbed. Free neuraminic acid was then adsorbed to the 'Dowex 1-formate', allowing all the free hexoses to pass through unadsorbed, and eluted therefrom with 0·3 *N* formic acid. Recovery with neuraminic acid standards prepared by hydrolysis of a preparation of bovine brain ganglioside[5] were found to be quantitative in this 3-column system. Paper chromatography was performed with Whatman No. 2 paper, using downward irrigation with a solvent system, butanol/acetic acid/water (4 : 1 : 5). Strips were developed utilizing the thiobarbituric acid spray[6] and ninhydrin reagent. Nitrogen was determined colorimetrically after hydrolysis and hexoses by the method of Sorensen-Haugaard[5].

One hundred random consecutive samples of cerebrospinal fluid were first tested for the presence of 'free' neuraminic acid by means of the thiobarbituric acid reaction. The concentration was shown to vary from 2–12 μgm./c.c. (mean = 5.60 ± 1.90 (*S.E.*)). Only eleven of the specimens showed values greater than 6 μgm./c.c. and nine of these were from patients in the process of being treated with electroshock therapy. On the other hand, seven other specimens which were from patients on this therapy did not show elevated 'free' neuraminic acid. Since the isolated glycoprotein fraction was shown to be negative for neuraminic acid with this reaction (without hydrolysis), the presence of 'free' neuraminic acid was indicated.

In the dialysable fraction (fraction II[2]) neuraminic acid was shown to be present by the thiobarbituric acid method before any further fractionation in amounts equivalent to those observed in whole non-dialysed cerebrospinal fluid. Further, individual dialysate fractions chromatographed on the 3-column system described above yielded an amount of neuraminic acid which had been adsorbed to the 'Dowex 1-formate' in quantities equivalent to the amount observed in the dialysate material before fractionation with a yield of 70–85 per cent.

Starting with 258.9 gm. of whole dialysate from 248 individual specimens (approximately 20 c.c. each) the material eluted with 0.3 *N* formic acid from the 'Dowex 1-formate' column was lyophilized, then further partitioned. By washing the lyophilized material above with cold methanol, two fractions, consisting of methanol-soluble and methanol-insoluble material were prepared. By successive precipitation of the methanol-soluble material with ether in the cold, six precipitates were obtained with generally increasing amounts of neuraminic acid (precipitates I–VI). The methanol-insoluble material was dried in air, taken up with water and separated by centrifugation into a water-soluble 'supernate *A*' and water-insoluble precipitate. The material in supernate *A* was not precipitable with ether. Determination of the content of neuraminic acid, nitrogen and hexose in these subfractions showed the presence of varying amounts of these substances in each of the fractions, the bulk of the neuraminic acid being found in the three fractions in Table 1. The absorption spectrum of the coloured product obtained with the thiobarbituric reaction in each of these three fractions was identical with that produced by our standard neuraminic acid. Each of the three fractions shown in Table 1 demonstrated one spot, respectively, on paper chromatography which was not identical to free neuraminic acid. With an R_F of the neuraminic acid standard of 0.13–0.15, precipitates I and VI and supernate *A* ran with slower R_F's as shown in Table 1, but one of these (precipitate VI) gave a strong 'free' neuraminic acid reaction with the thiobarbituric acid spray, and one (supernate *A*) gave a weak reaction with fluorescence. Hydrolysis of each of these fractions with 0.1 *N* sulphuric acid at 80° C. for 1 hr. produced a second more rapidly moving thiobarbituric acid-positive product with R_F 0.30–0.35 corresponding to the R_F of the product obtained by hydrolysis of the neuraminic acid standard under the same conditions.

Table 1. MOLAR RATIOS NEURAMINIC ACID, NITROGEN (AS AMINO-ACIDS), AND HEXOSE, AND R_F VALUES OF THREE FRACTIONS ISOLATED FROM DIALYSABLE CONSTITUENTS OF HUMAN CEREBROSPINAL FLUID*

	Molar ratios			
	Neuraminic acid	Amino acid	Hexose (glucose)	R_F
Supernate *A*	1.0	3.0	7.6	0.10
Precipitate I	1.0	2.6	4.1	0.10
Precipitate VI	1.0	4.0	5.6	0.07

* Hexosamines are totally absent from the dialysable fraction of human cerebrospinal fluid (ref. 2).

Since (1) the unhydrolysed fractions have slower mobility than the truly free neuraminic acid standard used, yet all showed the presence of 'free' neuraminic acid with the thiobarbituric acid reaction in test tube, (2) there was only one definite spot for each of these fractions in terms of ninhydrin-positive material and thiobarbituric-positive material, (3) hydrolysis produced an identical split product in the case of the neuraminic acid standard and of the three fractions, it is concluded that a sialic acid bound with hexose in ninhydrin-positive glycopeptide-like substances are present in dialysable form in human cerebrospinal fluid. These substances, not previously described in cerebrospinal fluid, are being further characterized and structurally studied. Since 'free' neuraminic acid is present in whole cerebrospinal fluid prior to fractionation, in isolated whole dialysate, and in isolated subfractions of the dialysate after column separation, all in equivalent amounts, these substances could not be derived by splitting from the larger molecular weight glycoproteins of cerebrospinal fluid during the isolation procedure. On the other hand, their biosynthetic origin, which *in situ* may be from the glycoproteins of cerebrospinal fluid, and their function, are the subjects of further study.

The 'whole dialysate' fractions were prepared by Mr. Peter C. Belval. This work was done with the support of grants from the U.S. Public Health Service (*B*-3612) and from the Scottish Rite Committee for Research on Schizophrenia.

Diminution of β-Glucuronidase Activity in Post-Heparin Human Sera

HAHN[1] discovered that after intravenous administration of heparin an enzyme appears in the blood, known as the clearing factor or lipoprotein-lipase. Later, Levy and Swank[2] observed in animal experiments an increase of tributyrinase. Skorepa and Todorovicova[3] found a 50 per cent rise of aliesterase activity and Pav and Wenkeova[4] indicated that, in addition to aliesterase, at least two other lipases are present in the post-heparin plasma. In this study it has been found that β-glucuronidase activity is significantly lowered in human post-heparin sera.

Blood serum β-glucuronidase activity was determined in normal individuals from 5 to 10 years of age, males and females, 1 hr. following an ordinary meal. Blood was drawn before and 15 min. after intravenous administration of 30 mgm. (30,000 units) of heparin. Dohrmann's modification[5] of Fishman's method[6] was used with an incubation period of 18 hr. A 43–64 per cent decrease of β-glucuronidase activity was found in the post-heparin sera. Cajani[7] noted that β-glucuronidase showed a 2,000-times greater affinity for heparin than for phenolphthalein β-glucuronide. Klesper and Dohrmann[8] demonstrated an anti-coagulant effect of β-glucuronidase *in vitro*. Kayahan[9] found a similar effect *in vivo* and also showed a decrease of lipæmia after administration of β-glucuronidase.

From these observations the following hypothesis, among others, appears reasonable: β-glucuronidase and heparin form a complex having not only an anti-coagulant power but also a lipoprotein–lipase activating or enhancing effect.

Excretion of 5-Hydroxy Indolyl-Acetic Acid after Surgery

ALTHOUGH the healing of a wound is an essentially local event, it must inevitably also involve wider metabolic processes in the whole organism. One metabolic excretory product of dietary tryptophan is 5-hydroxy indolyl-acetic acid (5-HIAA) derived via the intermediate metabolites 5-hydroxytryptophan (5-HTP) and 5-hydroxytryptamine (5-HT). Special interest has been devoted to this pathway because of its significance in carcinoid tumours. Certain of the metabolic and clinical changes produced by 5-HT may, however, also be important in tissue regeneration and the healing of wounds. As a method of investigating this, it was decided to study the excretion of 5-HIAA following wounding.

5-Hydroxytryptamine metabolism is notoriously difficult to study as it varies from animal to animal, and a number of confusions and contradictions observed in the past stemmed from this difficulty. The investigation reported here was carried out on human subjects. A 'standard experimental' wound was made by using patients with the same clinical condition and operation.

One of the most uniform operations is the repair of a moderate-sized inguinal hernia in the adult male. We therefore used 14 patients on whom this operation was to be carried out, by the same surgeon (G. T. W.). The patients were of a similar age-group (25–35 years) and all were admitted to the same ward. By this means it was hoped to standardize the form of mental and physical stress to which the patients were subjected. The diet was the regular hospital one, modified by exclusion of any items known to be high in tryptophan metabolites (for example, bananas, spinach, pineapple juice). The men were admitted to hospital 2 days before operation and no specimens were collected in the first 12 hr. The urine was then collected over each 24 hr. That passed during the day of operation was discarded. All specimens were collected in bottles containing 10 ml. glacial acetic acid and analyses made as soon as possible. Experiments showed, however, that if longer storage was unavoidable no significant change in 5-hydroxy indolyl-acetic acid content occurred for at least one week if the acidified sample was deep-frozen to − 20° C. Assays were made using a modification of the method of Udenfriend, Titus and Weissbach[1]. The results were expressed in mgm. of 5-hydroxy indolyl-acetic acid excreted every 24 hr. With this method the normal range for laboratory staff fell between the values 2–9 mgm./24 hr.

Table 1. URINARY 24-HR. 5-HIAA OUTPUT EXPRESSED IN MGM./24 HR.

Case No.	Day before operation	Days after operation First	Second	Third	Fourth
1	less than 1	10.5	—	—	—
2	1.2	9.9	—	—	—
3	4.5	8.5	—	—	—
4	2.6	6.4	—	—	—
5	6.0	6.1	—	—	—
6	3.8	10.6	13.2	7.4	6.8
7	4.0	9.4	5.9	7.0	—
8	6.3	11.3	8.7	—	—
9	8.7	10.2	4.5	10.2	—
10	10.3	15.8	8.1	6.7	—
11	1.5	10.6	2.9	4.8	5.8
12	4.9	24.2	11.6	10.6	—
13	5.8	17.2	—	10.2	12.1
14	4.9	10.1	5.1	3.5	6.1

Table 1 shows the pre- and post-operative levels of urinary 5-HIAA in the 14 patients examined. These figures indicate that with but one exception (case 5) the urinary 5-HIAA output was significantly increased on the first day following surgery. That such changes were not a function of a generalized increase in non-protein nitrogen metabolism was excluded in parallel urea nitrogen and creatinine measurements on the same samples. These showed no such changes after surgery. Parallel daily platelet counts were made in 6 cases; no significant correlation was evident. This shows that the alterations in 5-HIAA output are not related to an enhanced 5-HT metabolism consequent on an increase in post-operative circulating platelets. This does not of course exclude the possibility that an abnormal release of 5-HT from platelets may occur without change in the number circulating.

The urine samples from 6 cases were examined chromatographically. The results for 5-HIAA when assessed by a semiquantitative method were in general agreement with the colorimetric assays. It was also noted that in some instances certain other indole metabolites, notably indolyl acetic acid (IAA) and potassium indoxyl sulphate (indican), were also increased post-operatively and to approximately the same degree as 5-HIAA.

We thank Prof. F. A. R. Stammers, and Dr. G. B. Leyton of the Hollymoor Hospital for assistance with the chromatographic studies. This work was supported by the Medical Research Council and U.S. National Heart Institute (Grant No. *H*5772).

N-Acetyl-dopamine as Sclerotizing Agent of the Insect Cuticle

SCLEROTIZATION, that is, the hardening and darkening of the insect cuticle, is generally believed[1-3] to be due to the incorporation of *o*-quinones, the latter arising from the corresponding *o*-diphenols through the action of phenoloxidases. Tracer investigations[4] confirmed the view that tyrosine metabolites are incorporated into the cuticle. However, the nature of the metabolites has not been identified, though several *o*-diphenolic compounds have been isolated[5,6] from insect sources and tentatively regarded as precursors of sclerotin.

The diphenols discussed so far are all acidic in nature. We have recently detected an amine derivative, *N*-acetyl-dopamine, as a metabolite of tyrosine in blowfly larvæ (*Calliphora erythrocephala*) and have identified this compound as the tanning agent in puparium formation. The evidence is as follows:

(1) *N*-acetyl-dopamine (a compound not yet described in the literature) is a normal constituent of the larvæ. It can be demonstrated by paper chromatography of extracts from *Calliphora* larvæ ($R_F = 0{\cdot}80$ in butanol/acetic acid/water, 4 : 1 : 5; colour reactions: purple with diazosulphanilic acid, blue with Folin's reagent), and has been isolated and identified[7]. Quantitative determinations show that *N*-acetyl-dopamine is accumulated in late larvæ and disappears abruptly at the time of pupa formation.

(2) Radioactive *N*-acetyl-dopamine labelled at the β-C-atom is readily incorporated into the cuticle (Table 1). The incorporation is as high as that of tyrosine, within the experimental error. Also, if only the acetyl group of *N*-acetyl-dopamine is labelled, the radioactivity is found mainly in the cuticle[8]. From this we conclude that *N*-acetyl-dopamine is incorporated as a whole molecule.

(3) The enzyme phenoloxidase is presumably involved in the sclerotization process. This enzyme has recently been purified and obtained in the crystalline form in our laboratory[9], and its substrate specificity has been studied. Monophenols are not attacked, at least not with measurable velocity; the enzyme is a true *o*-diphenoloxidase. Also, *o*-diphenols with acidic side-chains, like protocatechuic acid, 3,4-dihydroxyphenylacetic and 3,4-dihydroxyphenylpyruvic acid, are not oxidized by the enzyme isolated from *Calliphora*. The best substrates are *N*-acetyl-dopamine ($K_m = 3 \times 10^{-3}$), dopamine ($K_m = 2 \times 10^{-4}$), and dopa ($K_m = 8 \times 10^{-3}$). Thus, the substrate specificity strongly suggests that not the dihydroxyphenolic acids isolated earlier but *N*-acetyl-dopamine is the sclerotizing agent in *Calliphora*.

(4) A survey of the tyrosine metabolism revealed remarkable differences between younger and older larvæ. In the early III instar (3–5 days old) tyrosine is mainly catabolized to *p*-hydroxyphenylpyruvic and *p*-hydroxyphenylpropionic acid. These metabolites have been identified by paper chromatography in combination with the tracer technique. In older larvæ (7–8 days old, about one day before pupation) these metabolites are only minor ones; the main product of injected tyrosine is *N*-acetyl-dopamine. Eventually, its 4-*O*-β-glucoside is also formed; this substance has also been detected in *Drosophila* pupæ[10].

Table 1

Substance injected	Percentage of radioactivity incorporated into the cuticle*
N-Acetyl-dopamine-β-^{14}C	63
N-(1-^{14}C-acetyl)-dopamine (ref. 8)	50
Dopamine-β-^{14}C	66
Tyrosine, generally labelled (ref. 8)	74

* Percentage of the recovered activity

(5) The shift in tyrosine metabolism from degradation (through transamination and oxidative decarboxylation) to the production of *N*-acetyl-dopamine is brought about by the hormone of the ring gland, ecdysone. It is inhibited by ligation or destruction of the ring gland. Thus, the hormone which causes pupa formation is also responsible for the metabolic changes which give rise to *N*-acetyl-dopamine.

Dennell[11] has postulated a metabolic pathway of tyrosine which, through unspecific hydroxylation and elimination of the side-chain, would give rise to *p*-dihydroxy compounds and *p*-quinones which are believed to be involved in sclerotization. This hypothesis, based on only a few model experiments, has been criticized by several authors[3,4]. The results described here do not support the hypothesis of Dennell; instead, they suggest the pathway of tyrosine metabolism in *Calliphora* as shown in Fig. 1.

It is likely that *N*-acetyl-dopamine is also the sclerotizing agent in other insects as well. By paper chromatography it has been identified in extracts from the mealworm (*Tenebrio molitor*, fully grown larvæ and adult insects) and from the desert locust, *Schistocerca gregaria* Forsk. On the other hand, protocatechuic acid has been identified as tanning agent in the hardening of the oothecæ of the cockroach, and the accumulation of its precursor, the 4-*O*-β-gluco-

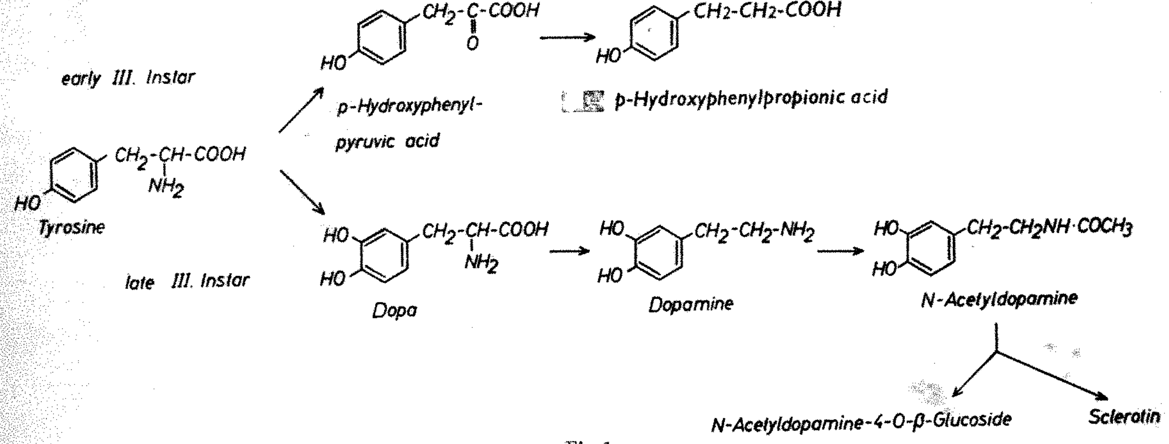

Fig. 1

side, has been demonstrated[12]. Production of ootheca, however, is a very specialized process, and its biochemistry may be different from the general picture of cuticle sclerotization outlined here.

Investigation of Phenolic Components of Brewing Materials by Gel Filtration

POLYPHENOLS, especially anthocyanogens, are of interest in brewing because of their tendency to form insoluble complexes with protein. These phenols are somewhat labile and difficult to isolate completely from colouring matter and low-molecular-weight contaminants. Separation can be achieved efficiently on 'Sephadex' and no reagents damaging to the phenols need be used.

A 2·5 × 30 cm. column of medium grade *G*.50 'Sephadex' was used. Before packing, the gel was allowed to swell in the eluting medium for several hours. The column was loaded with a 1-ml. sample and elution was carried out with water or 0·001 *M* phosphate buffer, *p*H 6·7. The eluate from the column was fed into an auto-analyser assembly where it was mixed continuously with diazotized *p*-amino benzoic acid. Any phenolic material gave coloured compounds, the absorption of which was measured at 420 mμ and continuously recorded.

Fig. 1 shows a typical elution curve obtained using a 1 ml. sample of unhopped brewery wort. The first peak ($K_D = 0$) contains about 30 per cent of the total nitrogen and consists of the high-molecular-weight material (> 8,000), which is mainly protein and melanin pigments. Low-molecular-weight simple phenols (for example, tyrosine) together with sugars and amino-acids are then eluted and, finally, a second peak of yellow material which is actually weakly adsorbed on the 'Sephadex' ($K_D > 1$). This fraction contains all the materials which yield red pigments on heating with hydrochloric acid (anthocyanogens). About 30 per cent of the total nitrogen is also present in this fraction, possibly as preformed soluble protein–polyphenol complex.

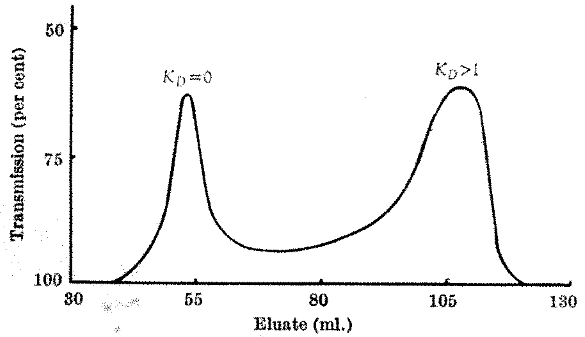

Fig. 1. Chromatography of unhopped brewery wort on a *G*.50 'Sephadex' column. Elution with 0·001 *M* phosphate buffer, *p*H 6·7. Material with $K_D = 0$ is excluded from the gel grain (mol. wt. > 8,000). $K_D > 1$ indicates adsorption on the 'Sephadex'

Nylon and polyvinyl pyrrolidone are known to improve shelf life of beer by adsorbing polyphenolic materials. 'Sephadex' columns are being used to investigate the nature of the polyphenols and their reaction with proteins, and to study similar compounds which occur in barley and hops.

PHYSIOLOGY

Climatic Variations of Plasma Potassium in Men

PLASMA potassium has been determined in South Indian and European subjects residing permanently in Madras, and in Europeans in Liège—all male, adult and healthy. The samples of blood were taken from the vein in the morning before breakfast and immediately centrifuged. The potassium was determined in the plasma by flame photometry. The meteorological data were obtained from the Regional Meteorological Center, Madras, and the Institut Royal Météorologique, Uccle, Belgium.

The plasma potassium of one European subject (J. G. H.) was repeatedly determined during several trips in India and Europe during June 1959–April 1961. The 24-hr. average temperature of each experimental day is plotted in the upper graph (Fig. 1).

The other subjects were tested only once, either during summer 1959 in India (9 White Europeans or Americans and 22 Indians), during winter 1960 in Europe (23 Europeans), during July–August 1960 in India (7 Europeans, 27 Indians), in September (24 Indians), during the monsoon (29 Indians), during December, January or May in India (respectively 17, 26 and 30 Indian subjects). The average potassium values and the standard errors (*m.* ± *s.e.*) are indicated for each group. The lower graph shows the mean temperature per month or half-month (Fig. 1).

No racial differences between Western and Indian men can be observed. On the contrary, climatic

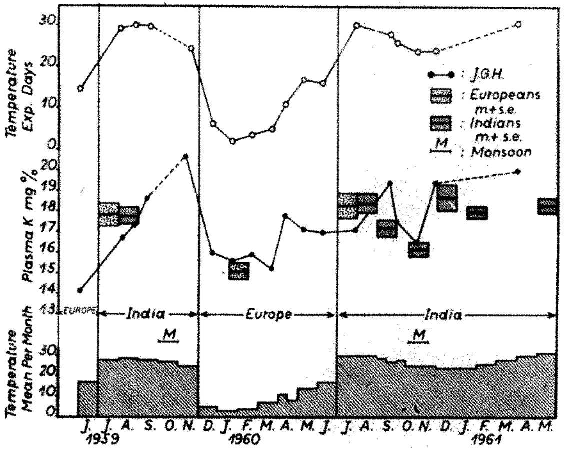

Fig. 1

variations are important and significant ($P < 0{\cdot}001$); potassium values are obviously correlated with dry bulb temperatures (Fig. 1). However, other potassium fluctuations seem to be superimposed over the main heat–cold effect. During the monsoon, the time–potassium curve shows a minimum corresponding to a sudden but slight decrease of temperature which in itself appears to be too small to affect the basic potassium value of the population later on, during December–January. There is no correlation between potassium values and relative humidity.

The potassium changes could be related to modifications in the activity of the suprarenal glands in hot and cold weather as suggested by previous investigations[1,2]. Influence of other meteorological factors and of sudden changes of temperature will be further investigated.

Effect of Glutamine on Intoxication caused by Ethyl Alcohol

IN their work on the effect of alcohol on the amino-acids of the brain of the rat, Kulonen and Häkkinen[1] observed that animals receiving glutamine seemed to be far less intoxicated than those receiving none. Ravel *et al.*[2] isolated a factor from *Streptococcus* bacteria which made this organism resistant to alcohol. The factor proved to be glutamine. This prompted me to examine the effect of glutamine on alcohol intoxication. For such purposes, these laboratories have devised a tilting-plane technique[3–5], which is described in the first-mentioned work as follows: The rat is placed on a plane with a rough surface; the plane is tilted and at a certain angle the animal slides down. An intoxicated rat slides down at a lower angle than a sober rat. The performance in intoxication is expressed as a percentage of the sober value.

Seven groups of rats were used, all of them originating from two litters, aged 2–5 months and weighing 200–300 gm. (females) or 250–450 gm. (males). The number of rats in the groups was 6, 8, 7, 10, 10, 8 and 8 (total 57). The animals were fasted overnight before the experiments. Alcohol was given by stomach tube as a 30 per cent v/v solution; glutamine was administered in the same solution as alcohol. Three replications were used in all groups except two, in which there was only one (4 and 5) from which alcohol in the blood was determined.

The results are given in Table 1. There is great intergroup variation in the effect of glutamine. There is no effect in the females with the smaller dosage of alcohol, but this might be due to the fact that the females tolerate alcohol well[6] and do not become markedly intoxicated by it even if no glutamine is given; with the larger dosage of alcohol the glutamine effect appears even among them. The groups of males show great variation in the glutamine effect; the only one in which there was no effect was a group with only one replication.

Glutamine did not affect the alcohol-level in the blood, as is seen from Table 1. Obviously the reason for the effect of glutamine lies in the part played by this substance in brain metabolism during alcohol intoxication, as shown by Kulonen and Häkkinen[1]. The degree of the effect varies greatly according to environmental conditions, and most probably also according to genetic constitution.

Effects on Sensory Nerves of injecting 5-Hydroxytryptamine into the Skin

CUTANEOUS mast cells in the rat differ from those of other species in that they contain, besides histamine, 5-hydroxytryptamine (5-HT)[1]. It is known that in the cat 5-HT excites certain cutaneous sensory nerve endings[2] and, since 5-HT is normally present in the rat's skin, there may be a possibility

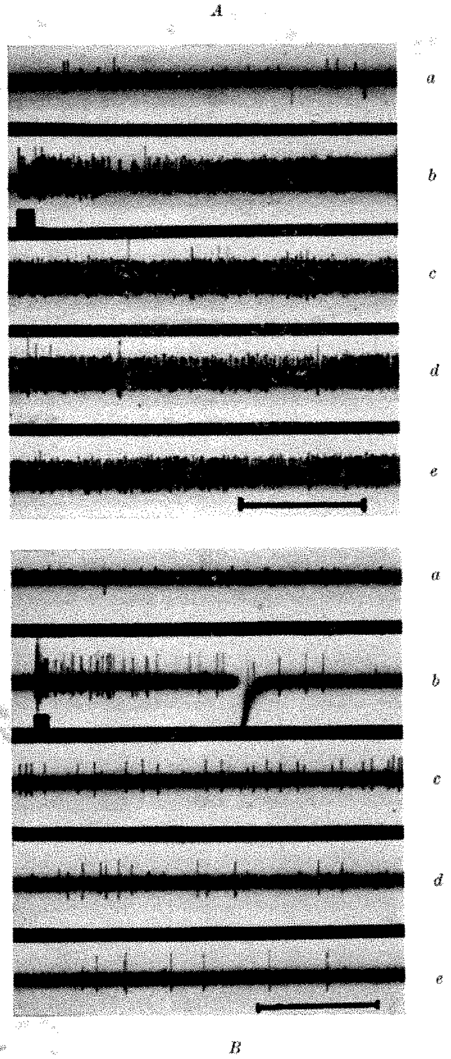

Fig. 1. Stimulation of sensory nerves produced by intra-arterial injection of 0·01 μmole 5-HT into the rat's skin (*A*) and the action of LSD (10 μgm./kgm.), administered intravenously 2 hr. previously, in antagonizing this effect (*B*). *a*, Spontaneous activity while artery is open; *b*, at signal, artery was closed and 0·1 ml. 5-HT injected; *c*, *d* and *e* show, respectively, the action of the drug 30 sec., 60 sec. and 105 sec. after time of injection. Time trace represents 5 sec.

that in this animal it has in certain circumstances a physiological action on cutaneous excitability. Results presented here show that the presence of 5-HT in small concentrations in the skin leads to a pronounced discharge of impulses in cutaneous sensory nerves.

Drugs were injected 'close-arterially' into a region of the skin innervated by a small branch of the saphenous nerve, from which impulses were recorded. Recordings were continued for 2 min. following each injection, after which time the blood supply to the skin was restored. All substances were dissolved in mammalian Ringer–Locke at *p*H 7·2 and the volume injected was 0·1 ml.

Injection of 0·01 μmole (1·8 μgm.) 5-HT produced a pronounced and long-lasting sensory discharge which began 1–2 sec. after completion of the injection (Fig. 1*A*). The latency of the response to 5-HT was always longer than to an injection of acetylcholine. The latter is known to excite sensory endings[3], but in these experiments the effective dose of acetylcholine was 50 times (0·5 μmole) larger than that of 5-HT.

The discharge evoked by 5-HT always occurred in two distinct phases. The first phase, consisting of a burst of impulses, lasted approximately 5 sec., after which time the activity diminished for 3–10 sec. Following this period of diminished activity, a renewed discharge occurred which then persisted for at least 2 min. When 5-HT injections were made after the rat had received 10 μgm./kgm. (3 μgm./300 gm.) lysergic acid diethylamine (LSD) intravenously, the second phase of the response gradually diminished, and after 2–3 hr. was abolished completely (Fig. 1*B*). The first phase of the response was little affected. LSD at no time affected the response evoked by mechanical stimulation of the skin or by an injection of acetylcholine.

The present work did not indicate whether 5-HT acted directly on certain sensory endings or whether the sensory stimulation was produced indirectly, for example, by vasoconstriction. However, the action of 5-HT could not be attributed to an indirect release of acetylcholine since hexamethonium (5 mgm./kgm. intravenously) did not affect the 5-HT response but did abolish the effects of injected acetylcholine. Histamine in amounts up to 1 μmole had little effect in these preparations, which also makes it unlikely that the 5-HT effect was due to a release of histamine.

According to Benditt[4], the concentration of 5-HT in the skin of the rat is approximately 2 μgm./gm. of tissue, which is roughly equivalent to 0·7 μgm./cm.^{2} of skin. Evans's blue injections indicated that, in the present experiments, at least 10 cm.^{2} (and probably more) of skin were perfused by the injected fluid. Since the total amount of 5-HT injected was 2 μgm., the maximum concentration in the skin would be about 0·2 μgm./cm.^{2}. It may be concluded, therefore, that disruption of cutaneous mast cells in the rat would result in strong stimulation of sensory nerves in the region affected. In view of the differences in mast cell content, it would be of interest to determine whether in other species histamine is more effective than 5-HT.

I thank Dr. J. H. Gaddum for his interest in this work, which was carried out during the tenure of a postdoctoral fellowship from the Life Insurance Medical Research Fund.

Influence of the Growth of the Walker 256 Carcinoma on Hepatic Transaminases

In the course of a study of enzymes associated with protein metabolism in the livers of tumour-bearing rats we have observed certain significant changes in the pattern of transaminase activities.

Female albino rats weighing 140–160 gm. were injected intramuscularly into the right thigh with 1 ml. portions of a suspension of Walker 256 carcinoma[1]. A control group received an intramuscular injection of 1 ml. 0·9 per cent saline. Throughout the experimental period both groups of rats were fed on synthetic diets described previously[2]. Groups of rats were killed at 3, 5, 7 and 9 days after inoculation and hepatic L-alanine-α-oxoglutarate and L-aspartate-α-oxoglutarate transaminases measured by colorimetric methods[3]. Under the experimental conditions used the mean weights of the tumours at 3, 5, 7 and 9 days after implantation were found to be 0·1 ± 0·08, 2·9 ± 0·5, 9·7 ± 0·9 and 14·6 ± 1·0 gm. respectively.

The concentration of hepatic alanine transaminase activity fell to about 50 per cent of the control value by the fifth day of tumour growth and this fall persisted over the remainder of the period studied. The total hepatic activity was also significantly lowered at the same stage of tumour growth (Table 1). There was a concomitant increase in the total activity of the closely related aspartate transaminase although the concentration of this enzyme was unaltered (Table 2).

Table 1. EFFECT OF TUMOUR GROWTH ON HEPATIC L-ALANINE-α-OXOGLUTARATE TRANSAMINASE ACTIVITY

Alanine transaminase activity*	Group	Time after injection 3 days	5 days	7 days	9 days
Per gm. liver	Control	0·76 ± 0·07 (5)	0·95 ± 0·06 (6)	1·02 ± 0·06 (6)	1·02 ± 0·06 (6)
	Tumour-bearing	0·61 ± 0·10 (6)	0·52 ± 0·03 (6)	0·49 ± 0·03 (6)	0·52 ± 0·09 (6)

Results are expressed as the means ± *S.E.* Figures in parentheses refer to the number of animals in each group.

* The enzyme activities are expressed as m.moles oxaloacetic acid formed per 10 min. at 37° C.

It has been shown previously[2] that these animals exhibited a considerable hepatomegaly throughout the experimental period. Thus it would appear that while the level of aspartate transaminase is keeping pace with the increase in liver size there is a definite depression of the alanine transaminase.

The activity of hepatic alanine transaminase has been shown to be related to the level of circulating glucocorticoids. Thus administration of corticotrophin or corticosteroids with gluconeogenic activity was found to cause a marked increase in the activity of this enzyme[4] whereas adrenalectomy resulted in reduced hepatic alanine transaminase activity[5]. It might be inferred, therefore, that the fall in hepatic alanine transaminase activity observed after 5 days of tumour growth might reflect a reduction in the level of circulating glucocorticoids. This view would be compatible with a previous finding that livers of rats bearing the Walker 256 carcinoma have an increased capacity to inactivate corticosterone as early as 30 hr. after tumour implantation[2].

This investigation was supported by a grant from the Medical Research Council.

HISTOCHEMISTRY

A Quantitative Histochemical Method for estimating Phospholipids

THE affinity of the 'Luxol' solvent dyes for phospholipids has been investigated. One of these dyes, 'Luxol' fast blue *MBS*, was introduced by Kluver and Barrera[1] as a myelin stain. It is a diarylguanidine salt of a sulphonated copper phthalocyanine dye. The dyes used in this investigation are diarylguanidine salts of sulphonated azo dyes. 'Luxol' fast blue *G*, 'Luxol' fast blue *ARN*, and 'Luxol' fast black *L*, have been found to form complexes with phosphotidyl choline, phosphotidyl ethanolamine, and phosphotidyl serine. Pearse[2] has already noted that 'Luxol' fast blue *MBS* forms precipitates with certain phospholipids in *in vitro* tests. He believed it was possibly an acid base reaction and that the base of the phospholipid replaced the base of the dye. He found his precipitates confined to the choline containing phospholipids. I have found that the dyes 'Luxol' fast blue *G* and *ARN*, and the phospholipids, phosphotidyl choline and phosphotidyl serine, form complexes stoichiometrically. Furthermore, there is a reversal of their common solubility in absolute ethanol (Table 1).

Table 1

Dye or dye complex	Solubility at 25° C. Water *p*H 7	Ethanol absolute	50 per cent ethanol
'Luxol' fast blue *G* 'Luxol' fast blue *ARN*	Insoluble	Readily	Slightly soluble
Dye-phosphotidyl choline complex	Soluble	Insoluble	Fairly
Dye-phosphotidyl ethanolamine complex	Soluble	Slowly soluble	Fairly
Dye-phosphotidyl serine complex	Soluble	Insoluble	Fairly

The phospholipid-dye complexes are soluble in neutral or alkaline water. They are not soluble in acidified water, however. These findings have been adapted as a staining method for phospholipids which I believe is quantitative or at least comparative. Riemersma[3] recently has stated that lecithin binds the anionic dye Ponceau 4*RS* in molecular proportions. He believes the quaternary ammonium group of the lecithin molecule to be involved, and that Ponceau 4*RS* can be regarded as a reagent for the positively charged choline group. However, this theory would not seem to account for the formation of a phosphotidyl serine-dye complex. In textile dyeing, direct dyes have been 'fixed' *in situ* with quaternary phosphonium compounds containing pentavalent phosphorus as well as with quaternary ammonium compounds.

The dye solution used was 0·1 per cent solution of either 'Luxol' fast blue *G* or *ARN* in absolute ethanol.

Measured quantities of lecithin and phosphotidyl serine in pyridine solution were placed on filter paper strips, and the pyridine allowed to evaporate completely. The strips were then placed in the dye solution for 1 hr. at room temperature. They were then rinsed in several changes of fresh absolute ethanol until all the uncomplexed dye was removed. Even leaving the strips for 24 hr. in absolute ethanol has not been found to remove the dye-phospholipid complex. The complex can be removed from the strips by eluting with slightly alkaline water. A 1 per cent solution of concentrated ammonia solution in water was used. The dye-phospholipid complex in this aqueous solution was then examined spectrophotometrically and found to be in direct proportion to the amount of phospholipid deposited originally on the strips.

Tissues of rat and dog brain were examined. The material was fixed in 10 per cent formalin, calcium formol or the following mixture[4]: water 90 ml., formaldehyde solution 10 ml., calcium chloride 1 gm., and cetyltrimethylammonium bromide 0·5 gm. Paraffin sections were cut of this material at 10μ, and the sections mounted on slides. When dried the paraffin was removed with xylene, and the sections rinsed in three changes of absolute ethanol and then placed in the above dye solution for 1 hr. at room temperature. They were then rinsed in several changes of absolute ethanol, cleared in xylene and mounted. In some cases 2 per cent pyridine was added to the dye solution, as this and small amounts of other bases appear to prevent any tendency for other tissue elements to stain. In the case of brain sections only phospholipid-containing tissue elements were stained. These findings were compared with the staining obtained with Baker's hæmatein method for phospholipids, and found to be very similar.

The affinity of these dyes for phospholipids is being further examined.

The samples of dye were supplied by the Organic Chemicals Department, E.I. du Pont de Nemours Co., Wilmington 98, Delaware.

An Improved Intravital Dye Iron-Prussian Blue Method for the *in vitro* Examination of Living Lymphatic Vessels

IN the nineteenth century Fodéra[1] used ferrous sulphate, converted to prussian blue, to demonstrate lymphatic vascular absorption in the experimental animal. With the introduction of pharmaceutical iron colloids, Turner-Warwick[2] found that 'Inferon' Benger (iron-oxide dextran complex) could similarly be used to demonstrate the afferent lymphatic vessels of the living female breast. For cleared specimens the staining method had certain disadvantages chiefly due to the solubility of prussian blue in alcohol during dehydration[3].

In the method described here, pharmaceutical 'Ferrivenin' Benger (colloidal saccharated iron oxide) is prepared as an isotonic solution (300 m.osmols/gm. water) by dilution in distilled water. When this solution (rendered visible by addition of patent blue violet) is injected intradermally by the method of Hudack and McMaster[4], it enters the fine lymphatic capillaries where it can be readily demonstrated by routine histology. For cleared whole specimens the disadvantages noted here[3] are overcome by treatment of the freshly stained material with alcoholic ammonia. This converts prussian blue to its alcohol-insoluble ammonium complex (stable in the presence of a very small excess of ammonia) and at the same time removes extraneous dye by alkali decomposition. The fixation method depends on the fact that 'Ferrivenin', though soluble in water, is insoluble in alcohols.

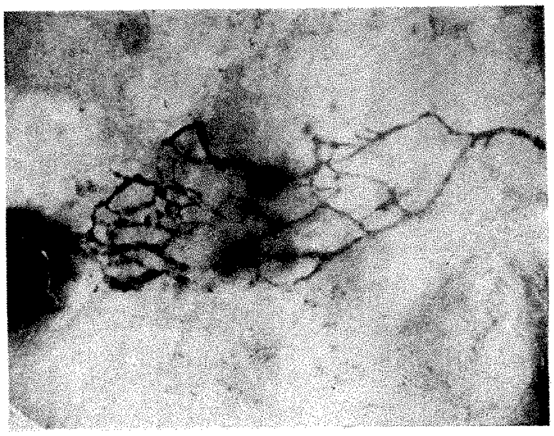

Fig. 1. Normal mouse ear. 10 min. before injection a light stroke with a blunt probe was made across the ear. (× *c*. 12·5. Cleared in oil of wintergreen)

Foci of abnormal lymphatic permeability, calibre and distribution are then clearly demarcated. (In practice iron diffusion from normal lymphatics is never seen (Fig. 1).) The illustration shows how this can be demonstrated by McMaster's experiment[5], in which a normal mouse ear is stroked transversely with a blunt probe 10 min. before injection. The cleared specimen shows a zone of increased lymphatic permeability at the line of the stroke. Distal to it the lymphatics are dilated, while the proximal vessels show a noticeable narrowing.

The method is as follows (sterile materials required for work on human beings):

(1) Dilute 5 ml. sterile 'Ferrivenin' Benger in 18 ml. sterile distilled water (about 21·7 per cent v/v).

(2) Add 2 ml. sterile isotonic patent blue violet solution (11 gm. per cent in distilled water) as a marker.

(3) Store in a rubber-capped vaccine bottle. This prevents ingress of moisture which lowers the osmotic pressure. (Solutions of less than 240 m.osmols/gm. water are of little value.)

(4) Inject this mixture by any technique based on that of Hudack and McMaster[4]. For work with small animals the microneedle of Florey *et al.*[6] is recommended for controlled studies. An 8 × red filter gives good contrast photography with patent blue violet.

(5) Resect the specimen with the minimum of trauma, in the mouse ear clamping should be avoided A delay of about 5 min (for example, for photography) does not harm the result in animal work In human skin special methods are necessary if delay is unavoidable

(6) Fix in a mixture of 10 parts 40 per cent aqueous formaldehyde and 90 parts absolute alcohol (for example, 74° proof industrial spirit) or 'Cellosolve' (2 ethoxy-ethanol B D H.) This latter substance does not have the hardening effects associated with alcohols (Leach, personal communication)

(7) After fixation for 4–12 hr , depending on size, the specimen is ready for routine histology A celloidin method (for example, that of Chesterman and Leach, personal communication) gives good results, since the embedded iron is not labile to acid distilled water and forms a well-defined blue 'mass' by Perl's method Paraffin and 'Estax' methods do not hold the iron so well and give a fine granular precipitate of prussian blue

(8) For cleared whole specimens, transfer the fixed material to 'Cellosolve' for 24 hr to remove traces of blue dye

(9) Trim and blot dry (Mouse ears should be trimmed off at the root)

(10) Stain 5–10 min in a warm acid ferro-cyanide mixture (for example, 1 part 25 per cent hydrochloric acid and 9 parts potassium ferrocyanide under a 60-W lamp)

(11) Observe in a clear solution (for example, distilled water) The injection site and (in thin specimens) the adjacent lymphatics should now be clearly visible Specimens more than 1 0 cm from injection site to cut edge may require a further 5–10 min staining to differentiate the remoter vessels

(12) Wash in tap-water and transfer to 'Cellosolve' containing 5 per cent v/v of strong (specific gravity 0 880) ammonia Shake The alkali decomposes extraneous dye, bleaching the specimen, the injected material is also changed to a deep navy blue colour

(13) Transfer to 'Cellosolve' containing 0 25 per cent v/v ammonia The number of changes depends on specimen size

(14) Clear in oil of wintergreen for 24–48 hr The specimen is then ready for photography Selected portions may be embedded directly in nitro-cellulose for histology or returned to 0 25 per cent ammonia 'Cellosolve' for storage

A method of delaying lymphatic flow for work on normal skin is now being investigated Abnormal skin may give good results without special measures if the flow-rate is pathologically reduced The technique of Hudack and McMaster[7] is used for the injection In practice a 'first' needle is not required if the injecting needle is first inserted point downward and then rotated

HÆMATOLOGY

Penicillin Sensitization of Paroxysmal Nocturnal Hæmoglobinuria Erythrocytes

THE ability of penicillin to function as a hapten can be detected by a hæmagglutination technique involving the use of penicillin-coated erythrocytes[1,2] It appears that all normal human erythrocytes as well as those from rabbits and sheep can be successfully sensitized with the antibiotic As part of an investigation to characterize the antibody concerned, it was found that the majority of sera giving positive direct hæmagglutination of sensitized cells suspended in saline failed to cause hæmolysis with added complement, although hæmolysis occurred if enzyme-treated penicillin-sensitized cells were used instead Since sera from patients with certain forms of auto-immune hæmolytic anæmia will also cause hæmolysis of paroxysmal nocturnal hæmoglobinuria erythrocytes, experiments were carried out to determine whether paroxysmal nocturnal hæmoglobinuria penicillin-sensitized cells would undergo hæmolysis in the presence of antibody and complement/properdin complex

Erythrocytes from a patient with paroxysmal nocturnal hæmoglobinuria and normal, group O, Rh-negative cells were sensitized with crystalline penicillin *G* as described previously[2] Hæmagglutination was tested for by adding two volumes of a 5 0 per cent suspension of washed cells in 0 85 per cent saline to six volumes of serial dilutions of known positive serum (titre 1/512) After incubation at 37 0° C for 1 5 hr , the tubes were centrifuged at 1,000 r p m for 1 min and hæmagglutination read by light resuspension of the cell deposits For the hæmolysis experiments dilutions of positive serum were made in fresh normal group AB serum Results are shown in Table 1

Table 1

	Hæmagglutinin titre	Hæmolysin titre
Penicillin-coated paroxysmal nocturnal hæmoglobinuria cells	<1/2	nil
Penicillin-coated normal cells	1/512	nil

Not only did paroxysmal nocturnal hæmoglobinuria cells fail to hæmolyse but also they failed to agglutinate at serum titres as low as 1/2, and repeated attempts to sensitize them with varying concentrations of penicillin were unsuccessful Antiglobulin tests performed on the washed cells were also negative Similarly, enzyme-treated penicillin-sensitized paroxysmal nocturnal hæmoglobinuria cells failed to react. When washed 'ghost' membranes, prepared by lysis of normal penicillin-sensitized cells and paroxysmal nocturnal hæmoglobinuria penicillin-treated 'cells in distilled water, were plated on to an agar plate seeded with a highly sensitive strain of *Sarcina lutea*, wide zones of inhibition surrounded the membranes from normal cells whereas no inhibition zones were noted around paroxysmal nocturnal hæmoglobinuria membranes This suggests that the phenomenon is due to a failure of adsorption of penicillin to paroxysmal nocturnal hæmoglobinuria cell stromal tissue

Further investigation showed that the adsorption defect was a selective one since paroxysmal nocturnal hæmoglobinuria cells were fully capable of adsorbing *Vi* antigen from a saline extract of acetone dried *Vi*-containing organisms, giving identical titres with *Vi* antiserum as did normal cells sensitized with *Vi* extract Penicillin sensitization of erythrocytes from a patient with congenital spherocytosis indicated that they adsorbed the antibiotic in the same way as normal cells

The nature of the stromal abnormality of paroxysmal nocturnal hæmoglobinuria cells has not been determined Electron microscopy has revealed a patchy pitted surface with many clefts[3] Chemical studies have indicated a decrease in phosphorylcholine and an increase in phosphorylserine[4], although these findings have since been refuted[5] Similarly, abnormalities in stromal lipoprotein described by Munn and Crosby[6] may be dependent on variations in the dietary consumption of fat[7] A marked reduction in the uptake of radioactive phosphorus by paroxysmal nocturnal hæmoglobinuria cells as compared with normal cells has been described[8] and also a deficiency of acetylcholinesterase[9], but the significance of these observations is obscure

Effect of Anæmic Anoxia on Erythropoiesis of Nephrectomized Dog

Experiments performed on the dog suggest that the kidney is a source of production of an erythropoietic factor. Erythropoiesis is suppressed by bilateral nephrectomy while this function is maintained after ureteral ligation[1,2] Furthermore, erythropoietin plasma-level decreases after nephrectomy in an anæmic dog and is unaffected by ureteral ligation, despite the same accumulation of metabolic waste products[3] The present investigation was designed to determine whether it is possible to stimulate erythropoiesis in dogs made anæmic by severe bleedings performed after nephrectomy

Control measurements were made in 22 normal dogs, eight dogs were subjected to bilateral nephrectomy only (details and results concerning this group have been reported elsewhere[2]), eight dogs were severely bled immediately after nephrectomy three daily withdrawals of blood were made on four animals (each bleeding was equal to 2 5 per cent of the body-weight), four other animals were bled twice only and the quantity of blood withdrawn each time was equal to 2 per cent of the body-weight The first bleeding was performed 30 min after the surgical procedures The volume of blood was maintained by infusion of dextran

Erythropoiesis was measured by numeration of marrow erythroblasts, reticulocytes and plasma iron turn-over carried out 3 days after nephrectomy Results are summarized in Table 1

Normal values for the percentage of erythroblasts and reticulocytes and for turn-over of plasma iron were respectively 23 3 per cent, 3 1 parts per thousand and 0 78 mgm /kgm /day Three days after nephrectomy, these values averaged 0 6 per cent, 0 9 part per thousand and 0 24 mgm /kgm /day respectively When bleedings were performed, no stimulation of erythropoiesis could be disclosed on the third day, despite severe anæmia (hæmatocrit between 18 and 29 per cent) The same percentage disappearance of erythroblasts (1 8 per cent) and percentage reduction of reticulocytes (0 8 per cent) occurred as in non-anæmic nephrectomized dogs. the turn-over of plasma iron was of the same magnitude (0 26 mgm /kgm /day) in both groups

Table 1 Effect of Bleeding on the Erythropoiesis of Nephrectomized Dogs

Group	No	Hæmatocrit (per cent)	Reticulocytes (parts per thousand)	Erythroblasts (per cent)	Iron turn-over mgm / kgm /day
I Normal	22	49 ± 0 96	3 1 ± 0 68*	23 3 ± 2 23	0 78 ± 0 06
II Nephrectomized	8	44 ± 1 57	0 9 ± 0 41	0 6 ± 0 18	0 24 ± 0 05
III Bled after nephrectomy	8	24 ± 1 43	0 8 ± 0 18	1 8 ± 0 50	0 26 ± 0 04
P of differences					
I–II		< 0 01	*N S*	< 0 001	< 0 001
II–III		< 0 001	*N S*	< 0 05	*N S*

* Values are means ± standard error of the mean

According to these observations, it can be concluded that in the absence of the kidney there is no more regulation of erythropoiesis probably because the source of erythropoietin has been removed This does not support the observation published by Erslev[4], who has demonstrated an increased erythropoietic activity in nephrectomized bled rabbits

Nevertheless, our results lead to the same conclusion as that drawn from the disappearance of erythropoietin from plasma of anæmic dogs following nephrectomy These observations suggest that, in the dog, there is no other site of production of an erythropoietic factor outside the kidney

As has been shown by previous experiments[2], retention of toxic products does not seem to be responsible for the non-regulation of erythropoiesis, after nephrectomy, but this possibility is now under investigation

PATHOLOGY

Cariogenicity of Common Sugars as evaluated in the Artificial Mouth

The artificial mouth is a device for simulating *in vitro* the principal oral conditions presumably involved in dental caries[1] Qualitatively, the *in vitro* lesions produced in human teeth are similar to those produced naturally[2-4] The method has been used for the quantitative evaluation of anti-caries agents and dentifrices[5-7]

The procedure consists of exposing extracted human teeth to a mixed culture of oral micro-organisms[5,6] A bacteriological medium is dripped continuously on the tooth, which is covered with a mixed bacterial plaque derived from oral micro-organisms The rate of softening of the external enamel is followed by measurements of the change of hardness The sugar used in the medium has generally been D-glucose, the concentration of which has been shown to be very important in determining the type of attack[8] When the sugar was present in low concentrations (< 0 10 gm /100 ml), the teeth were not attacked unless decalcified dentin was present For concentrations of 0 5 gm /100 ml , the attack was mainly a decalcification, and the dentinal matrix was not attacked For concentrations of about 0 2–0 3 gm /100 ml , both decalcification and dentinal matrix destruction occurred

The present work was done in order to determine whether other common sugars can be used instead of D-glucose and to compare their cariogenicity under these conditions

The effect of the following sugars in the bacteriological medium used in the artificial mouth was studied D-glucose, D-fructose, D-mannose, D-galactose, lactose, maltose and sucrose Soluble starch was also included in the investigation The original plaques were grown in the presence of these sugars, and they were also present during the tooth-softening period Some difference in amount of bacterial plaque formation was noted, but the amount was always sufficient to cover the experimental tooth surfaces The amount of sugar (0 3 gm /100 ml of hexose equivalent) was the same as the optimal amount found previously for D-glucose to produce maximal decalcification and dentinal matrix destruction

The average softening-rates are given in Table 1 The rate for D-glucose was similar to that previously reported[6] and was used as the standard for comparisons For D-fructose, D-mannose and sucrose, the softening rates were similar to those for D-glucose Those for D-galactose, maltose and lactose seemed to be less than for the other sugars However, analysis by the Student *t* test indicated that only maltose was significantly different from D-glucose at the 0 01-level of confidence

When soluble starch was present in the medium, the teeth showed no change during the experimental period

Table 1 COMPARISON OF DIFFERENT SUGARS* ON THE RATE OF SOFTENING OF ENAMEL SURFACES IN THE ARTIFICIAL MOUTH FOR 8 HR

Sugar	No of teeth	Softening-rate† (percentage per hr)	*S D*
D-Glucose	23	6 1	2 4
D-Fructose	12	6 2	3 3
D-Mannose	12	7 3	3 1
D-Galactose	10	4 8	2 2
Lactose	12	4 9	2 3
Maltose	12	3 8	1 8
Sucrose	16	5 2	3 8
Soluble starch	12	0 0‡	—

* Present as hexose equivalent of 0 3 gm /100 ml of culture medium

† $\dfrac{\text{Decrease in Knoop hardness No.} \times 100}{\text{Time (hr)} \times \text{initial hardness}}$

‡ The teeth of this group all showed a slightly greater hardness than the initial value

The *p*H and titratable acidity of the effluent media were measured after the 8 hr operation of the artificial mouth The absolute values have no significance, since they are dependent on the rate of flow For all the effluent media which contained sugars, the *p*H was in the range 5 0–6 0, whereas that of the original media was 6 4–6 7 The production of acids was also shown by an increase of the titratable acidity (to *p*H 8 0) of the medium, but no consistent pattern was evident for the sugars For the soluble starch solutions, the *p*H was 6 3–6 4, and some titratable acid was formed

The two most common dietary sugars, D-glucose and sucrose, thus produced similar rates of softening of teeth in the artificial mouth when incorporated in the bacteriological medium This result is not surprising since many bacteria can use either interchangeably Slower rates produced by galactose and lactose, if significant, might be explained by their utilization by fewer micro-organisms, actually the oral micro-organisms did utilize them and produced enamel softening

The lack of any softening by soluble starch is probably related to the slight ability of the oral micro-organisms to break down the starch to fermentable sugars This particular result has no direct relation to oral conditions, however, since saliva contains amylases which hydrolyse starches at least partially to fermentable oligosaccharides The low rate produced by maltose is interesting in this connexion since its rate was the lowest of the sugars, and it is a major product of amylase action

As shown earlier[9], the softening produced by the medium containing D-glucose was completely prevented in the presence of calcium phosphate solutions which will reharden softened surfaces Presumably, the effects of other sugars would be similarly inhibited

IMMUNOLOGY

Reduced Antibody Response in Thymectomized Rabbits

DESPITE considerable experimental work, the function of the thymus has not yet been clearly delineated Although it is an organ rich in lymphoid cells, it differs from other lymphoid organs in its failure to produce significant amounts of antibody after antigenic stimulation[1–3] and in its embryonic origin from the endoderm of the third pharyngeal pouch The thymus is largest relative to body-weight during the period of immunological deficiency early in life and it becomes progressively smaller after the immune responses are fully developed[4], a growth pattern which suggests its relation to the development of immunological mechanisms The occurrence in the same patient of the two rare conditions, namely, benign thymoma and acquired agammaglobulinaemia[5–7], suggested a relationship of the thymus to immunological processes Thymectomy in adult or even in young rabbits[6,8,9] had no effect on their antibody response, but subtotal thymectomy performed on young guinea pigs caused reduced antibody formation in some of the experimental groups[10]

Other work which suggested neonatal thymectomy in rabbits was that of Mueller *et al* [11] Removal of the bursa of Fabricius, a lymphoid organ of endodermal origin, also reduced antibody production Because of these observations thymectomy in the experiments reported here was performed in neonatal rabbits the antibody response of which was assessed at a later time. A preliminary report has been presented[12]

New Zealand albino rabbits were anæsthetized with ether and their thymuses were removed through a median incision of the chest wall either by surgical dissection or with a glass pipette connected to an aspirator The incision was closed with silk suture Litter mates were either sham operated or left unoperated as controls Three separate experiments were performed In the first, thymectomy was carried out at five days and the rabbits were challenged with bovine serum albumin 50 mgm /kgm of body-weight intravenously at 7–8 weeks of age The anti-bovine serum albumin content of the serum was measured by the capillary precipitin method (Table 1) and by the ammonium sulphate precipitation technique of Farr[13] (Table 2) These tables show that the thymectomized rabbits had a diminished antibody response to bovine serum albumin as compared with litter-mate controls

In the second experiment, the rabbits were thymectomized at 5–7 days of age and challenged with bovine serum albumin at 5–7 weeks The results of similar determinations in this series are given in Tables 3 and 4 Although the thymectomized rabbits responded less frequently and, as a group, formed less antibody than the controls, the difference was not significant

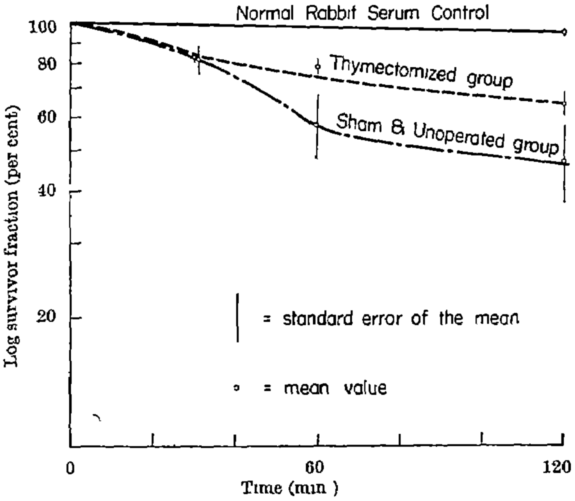

Fig 1

In the third experiment the rabbits were thymectomized at 0–3 days and were immunized with 8 × 10^9 T_2 coliphage particles/kgm at 14–18 weeks of age Phage neutralization-rates[14] on 7-day serum samples are given in Fig 1 The thymectomized rabbits formed significantly less neutralizing antibody against the bacteriophage than did the control animals

These experiments indicate that thymectomy in the new-born rabbit depresses its antibody response at maturity In the first and third experiments the differences between the thymectomized and control groups were highly significant The second experiment showed the same trend although the results fell below the level of significance, reflecting in part a poor antibody response of control rabbits Also, it is probable that the time of thymectomy in the new-born rabbit is very critical because significant results were recorded only when the operation was performed at 5 days of age or less Very early thymectomy may be especially important in animals such as the rabbit, which appear immunologically more mature at birth than animals such as the mouse in transplantation and tolerance studies[15]

These experiments on rabbits, and recent work showing that transplantation barriers can be bridged in mature mice thymectomized in the neonatal period[16,17], point to the importance of the thymus in the development of the immune response Whether this effect is consequent to humoral or cellular mechanisms remains to be defined The experiments of Comsa[18] and Metcalfe[19] suggesting that extracts of thymus can cause lymphocytosis point to a humoral mechanism Whether neonatal thymectomy quantitatively reduces the total number of cells available in the lympho-reticular system or whether it removes elements which are qualitatively distinct is likewise undefined Our present hypothesis is that the thymus in new-born mammals and the bursa of Fabricius in newly hatched fowl represent important centres for centrifugal distribution of immunologically competent cells to other lymphatic organs A similar concept has been discussed elsewhere[20-22]

ANATOMY

Prediction of Muscle Content of Steer Carcasses

With the emphasis in beef production shifting rapidly to the development of cattle with a high lean content, it is becoming increasingly important that methods should be available whereby accurate prediction of carcass muscle can be made The accepted practice of using measurements of a cross-section of the longissimus dorsi muscle has been shown to have a low degree of accuracy[1,2]

It was found by Orme *et al* [3] that the weights of some individual muscles and muscle groups of a line of mature Hereford cows were closely correlated to their total carcass muscle, and these authors suggest that the relationships might apply over a wide range of carcasses

This communication, based on the complete individual muscle dissection of thirty-five steers of various breeds and ages, records the similarity of results obtained irrespective of breed and age, and indicates the greater degree of accuracy attained by proper anatomical dissection of all muscles than by either dissection of lean from commercial cuts[1], or the gross separation of lean from other tissues[3] The steers dissected were drawn from the following breeds Poll Hereford, 19, Hereford, 4, Brahman/Hereford Crossbred, 8, and $\frac{3}{4}$ Bred Brahman, 4 The ages of the cattle ranged from six months to four years The dissection technique, to be published elsewhere, was carried out by one individual and was less time-consuming than the procedure reported by Walker[4]

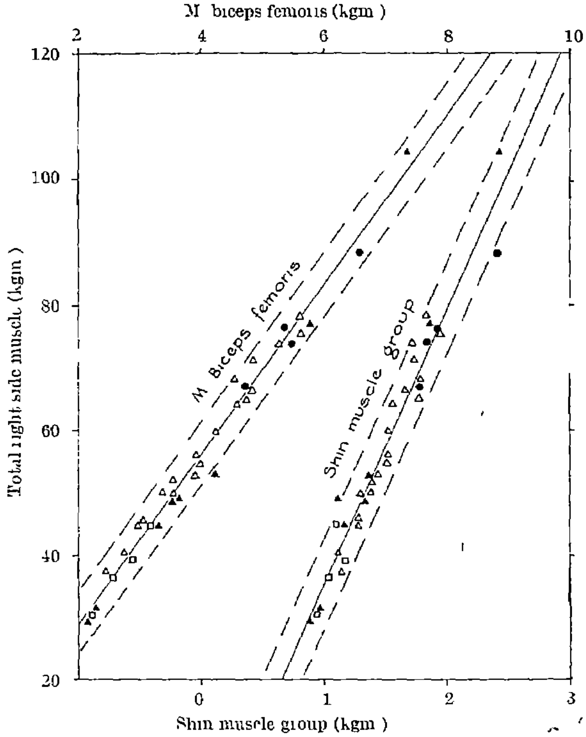

Fig 1 Regression of total right side muscle weight on the weight of biceps femoris muscle and shin muscle group M biceps femoris, $y = 1,344 + 13\ 6578\ x$(gm), $r = 0\ 9908$ Shin muscle group, $y = -7,905 + 43\ 6127x$(gm), $r = 0\ 9760$ □, Hereford, ⊿, Polled Hereford, ▲, Brahman × Hereford, ●, $\frac{3}{4}$ Bred Brahman

All muscles were weighed and data from the analysis of the weights of selected individual muscles versus total carcass muscle weight of this heterogeneous group of cattle are given in Table 1 The data presented are for right sides of carcasses only, and justification for the assumption of bilateral symmetry will be published later

Coefficients of correlation obtained were significantly better at the 5 per cent level than those published by Orme *et al* [3] This indicates that data

Table 1 Regression of Total Right Side Muscle Weight on Weight of Certain Muscles or Muscle Groups for Thirty-Five Steers

Muscle	Regression equation	Error Syx*	Error $Sbyx$†	Correlation coefficient r	Significances of differences of correlation coefficients‡ t
Biceps femoris	$y=1,344+13\ 6578x$(gm)	2,330	0 3234	0 9908	2 258§ (ref 3)

§ Significant at $P=0\ 05$

¶ Significant at $P=0\ 01$

obtained from my series of dissections are more consistent than those of Orme *et al* , and this probably reflects the differences in the accuracy of the various dissection techniques Table 1 shows that the total weight of the dissected individual muscles of the shin group is a more valuable prediction index than the muscle content of the commercial foreshank[1]

The relationship between the total carcass muscle weight and the weights of the biceps femoris muscle and the muscles of the shin group is shown in Fig 1, and indicates the value of a large individual muscle or a group of small muscles, for predicting total carcass muscle weight over a wide range of steer carcasses

Statistical analysis revealed no significant differences between the breed groups within the series, when compared for the weight of biceps femoris muscle, longissimus dorsi muscle, and the muscles of the shin group This result is interesting when the striking difference in the external shape of the extreme types of cattle in this series is considered

When the animals were grouped into the following age-groups 6–12 months, 3, 13–18 months, 7, 19–24 months, 7, 25–30 months, 10, and greater than 30 months, 7, with the same muscles and muscle group as above, statistical analysis could not detect any effect of age on the regression of the total muscle weight on individual muscle weights It is apparent that the major age differences expected in the light of the work of Hammond[5] were no longer apparent by the age of six months Further information on the age effect on muscle distribution in cattle is urgently needed

Statistical comparison of the regression coefficients of my data with those of Orme *et al* [3] gave significant differences with three of five muscles No explanation of these differences is attempted in this preliminary communication, which, it is hoped, will stimulate further investigation of the use of individual muscle dissection as a valuable tool for prediction of total muscle in various species, wherever these data are needed in research or commerce

This work was financed partly by the Commonwealth Scientific and Industrial Research Organization which also provided laboratory accommodation I thank Prof John Francis and Mr N D S May for their support and advice during the course of the work, Mr A Howard for statistical advice and Mr L E Brownlie for assistance with the calculations

Growth of Human Striated Muscle

IT has often been stated that hyperplasia in human striated muscle is completed early in fœtal life This belief is based on the single report of total fibre counts in the sartorius muscle by MacCallum[1] and on the negative findings of Cuajunco[2] that in the biceps brachialis muscle division of fibres could not be detected after mid-gestation Tello[3], on the other hand, deduced from the morphological appearances that new fibres might appear in human muscle up to the time of birth

MacCallum's conclusion was based on fibre counts made on five fœtal specimens and one specimen at term Two figures were given for the latter, there is no indication that the other figures represented more than one estimate per specimen

During a study of muscle changes in human malnutrition it was found that in controls the number of fibres and of sub-sarcolemmal nuclei continued to increase during the late fœtal period The number of nuclei increased by a further factor of 10 or more between birth and adult life

Sartorius muscle was examined at autopsy from 3 still-births (2 premature 1 at full term) 2 well-nourished infants and 2 adults One whole muscle was removed in each case, cleaned of visible fat and fixed in formol-saline Complete transverse blocks were taken from the midpoint and from the proximal and distal quarters of each muscle Slides of the whole muscle in cross-section were cut of uniform thickness and stained with hæmatoxylin and eosin

Low-power projections were made through a photographic enlarger and the area of primary bundles was outlined on paper and measured by planimetry A millimetre scale was similarly projected High-power projections were then made through a standard microscope using a strong light source Counts of individual fibres and sub-sarcolemmal nuclei were made as they were traced on paper, from fields which were as representative as possible of the total area included in the low-power projection The high-power scale was obtained from a hæmocytometer slide 200–500 fibres were included in each count (at least 100 in the case of adult specimens), and at least 5 areas were counted in each slide

Table 1 TOTAL COUNTS OF FIBRES AND SUB-SARCOLEMMAL NUCLEI IN TRANSVERSE SECTION OF HUMAN SARTORIUS MUSCLE

Age	Body-length (cm)	No of fibres ($\times 10^{-3}$) ($\pm$ *S E*)	No of nuclei ($\times 10^{-3}$) ($\pm$ *S E*)	No of nuclei ($\times$ body-length $\times 10^{-5}$)
31/52 fœtus	38	64 ± 3 15	34 ± 2 10	13
33/52 fœtus	44	76 ± 2 09	42 ± 2 29	18
Full-term	50	101 ± 4 75	56 ± 1 27	28
4 months	58	134 ± 7 36	64 ± 2 58	37
13 months	76	128 ± 5 35	85 ± 2 59	65
64 years	162	103 ± 3 59	233 ± 9 84	376
74 years	156	114 ± 2 70	201 ± 10 5	313

No significant differences in morphology or in the counts were found in transverse sections of the proximal and distal quarters of the muscle as compared to the midpoint The mean figures of total fibres and sub-sarcolemmal nuclei in sections from the midpoint are given in Table 1 Figures in the final column are an approximate index of the total number of sub-sarcolemmal nuclei in the whole muscle, there is an error due to the differential growth of the lower limbs which tends to underestimate the numbers in the adult relative to those of the infant

The fibre number is approximately doubled between the 32nd week of fœtal life and 4 months of age It is not certain whether the increase is complete at full-term A steady increase in sub-sarcolemmal nuclear number appears to accompany all stages of muscle growth

No evidence of splitting of fibres was found which could not be attributed to artefact, on the other hand, in the fœtal specimens the appearance of some fibres in longitudinal section strongly suggested a fine tapering to a termination, accounting for some of the marked variation in fibre diameter which was observed on transverse section. No process either of mitotic or amitotic division of sub-sarcolemmal nuclei could be found, and no centrally placed nuclei were seen.

The picture suggests that at least during this stage of fœtal development the increase in fibre number in transverse section may be due to lengthening of pre-existing fibres rather than to splitting[4]. The recent *in vitro* studies of Cooper and Konigsberg[5] offer a possible explanation of the increase in numbers of sub-sarcolemmal nuclei, in that mononuclear interstitial 'myoblasts' may be progressively incorporated into the developing fibre.

Although the problem may be different in the case of the mononuclear cardiac cell, it is of interest that growth of the piglet's heart appears also to involve a steady nuclear proliferation[6].

RADIOBIOLOGY

Kinetosomes of Tetrahymena

It has been reported that the kinetosomes of the ciliate *Tetrahymena* contain deoxyribonucleic acid (DNA)[1,2]. This finding is of considerable interest in view of its possible bearing on the problem of the function of the kinetosomes. Attempts have been made to use high-resolution autoradiography as a sensitive cytochemical tool in the detection of kinetosomal DNA in *Tetrahymena*.

The organisms, *Tetrahymena pyriformis* strain *S*, were grown in axenic culture on a proteose-peptone, yeast extract medium at 28·5° C; fresh cultures were used for each experiment, which was performed during the logarithmic phase of growth. The DNA of the organisms was labelled by incorporating precursors into the culture medium; tritiated thymidine of 200 mc./m*M* specific activity, tritiated cytidine 99 mc./m*M*, and tritiated uracil 123 mc./m*M* were used at concentrations of 0·5 μc./ml. to 5 μc./ml. After 24 hr. the organisms were fixed in an acetic acid–alcohol mixture the osmotic pressure of which had been adjusted to that of the culture medium. Whole mounts of the specimens were made by drying down on to clean slides. Autoradiographs were prepared with Kodak *AR* 10 stripping film, and were exposed in light-tight boxes at 5° C. and developed in Kodak *D* 19*b*. Controls were run consisting of specimens which had not received any radioactive material and of specimens which had been incubated with deoxyribonuclease and with ribonuclease.

No evidence for the existence of kinetosomal DNA in *Tetrahymena* was obtained from these experiments. Autoradiographs of tritiated thymidine showed strong nuclear labelling after an exposure of 40 days, there was no nuclear labelling after treatment with DNase, and the intensity of labelling was unaffected by the use of RNase. In some experiments a very low level of random cytoplasmic labelling was observed, and it was apparently removed by DNase. However, even after 61 days exposure this was only just at the level that could be regarded as sufficient under the most favourable conditions to indicate positive labelling[3].

Tritiated cytidine and tritiated-uracil are incorporated into both the nucleic acids of *Tetrahymena*, so the interpretation of the results depends on the enzyme digestions used. When RNA had been removed by enzyme digestion, there was no detectable cytoplasmic labelling above background, after 40 days exposure. There was strong labelling in the nucleus from tritiated-cytidine but only rather weak labelling from tritiated-uracil; the nuclear labelling was removed by DNase.

An examination of the autoradiographs under phase-contrast conditions showed that the kinetosomes were still identifiable after preparation of the specimen and, with the resolution available in tritium autoradiographs using Kodak *AR* 10—about 0·75μ—it would have been possible to see ordered rows of silver grains in the emulsion if the kinetosomes had become labelled. A calculation of the amount of tritium needed to produce a single silver grain in the autoradiograph after 40 days exposure shows that there is probably less than 10^{-15} gm. DNA per kinetosome in *Tetrahymena*.

The sensitivity of these experiments is not high enough to detect the DNA found by Seaman[2] in the isolated kinetosomes of *Tetrahymena*.

This work was carried out in the Wheatstone Laboratory, King's College, London, with the help and advice of Prof. J. T. Randall and advice on autoradiography from Dr. S. R. Pelc.

Specific Radioprotective Effect of the Mitochondrial Matrix

The ability of the cellular contents to protect enzyme molecules from the destructive action of ionizing radiation is now clearly recognized[1]; but there is little quantitative information concerning the specific radio protection offered by the natural intracellular milieu. Irradiation of whole animals suggests that this natural environment affords a high degree of protection from the indirect effects of aqueous radicals and perhaps from direct effects as well[2]. The specificity of this protection can be demonstrated by the irradiation and assay of enzymes uniquely associated with organelles within and without their natural cellular environment. For example, diphosphopyridine nucleotide-pyrophosphorylase, an enzyme contained exclusively in the cell nucleus, is many times more resistant to X-rays in isolated nuclei than is an equally active solution free of nuclei[3]. In the experiments to be reported, glutamic dehydrogenase, an enzyme believed to be confined to the mitochondrial matrix[4,5], has been irradiated without and within the intact mitochondrion.

Mitochondria were prepared from albino rat liver homogenates in 0·25 *M* sucrose – 1 m*M* ethylenediamine tetraacetate *p*H 6·7 (ref. 5). After centrifugation of the nuclei, erythrocytes and cell debris at 7,000 *g* × min. the mitochondria were sedimented at 35,000 *g* × min. The mitochondrial pellet was resuspended in fresh sucrose and sedimented again at

Table 1. Irradiation of osmotically disrupted mitochondria (0·025 *M* sucrose) in which nearly half the glutamic dehydrogenase activity was extramitochondrial. Activities are expressed as *ΔD* 340 mμ per 5 min.; the numbers in parenthesis are the percentages of the control unirradiated suspensions

	Unirradiated	90,000 r.	150,000 r.
Total activity ('Triton *X*-100')	0·088 (100 per cent)	0·074 (84 per cent)	0·045 (51 per cent)
Activity of free enzyme (supernatant)	0·038 (100 per cent)	0·017 (45 per cent)	0·004 (9 per cent)
Intramitochondrial activity (difference)	0·050 (100 per cent)	0·057 (114 per cent)	0·041 (82 per cent)

Table 2. Irradiation of intact liver mitochondria to which pure beef liver glutamic dehydrogenase has been added. Activities are expressed as *ΔD* 340 mμ per 5 min.; the numbers in parentheses are the percentages of the control unirradiated suspension

	Unirradiated	76,000 r.	133,000 r.
Total activity ('Triton *X*-100')	0·240 (100 per cent)	0·112 (47 per cent)	0·092 (38 per cent)
Activity of free added enzyme (supernatant)	0·149 (100 per cent)	0·017 (11 per cent)	0·006 (4 per cent)
Intramitochondrial activity (difference)	0·091 (100 per cent)	0·095 (104 per cent)	0·086 (95 per cent)

7,000 $g \times$ min. to remove residual nuclei and again centrifuged for 35,000 $g \times$ min. This last centrifugation was repeated until the supernatant was clear. Suspensions of mitochondria were irradiated with 250 kV. unfiltered X-rays in aerated, ice-cooled glass beakers and a ferrous ammonium sulphate dosimeter was used. Glutamic dehydrogenase activity was assayed by following the oxidation of DPNH in the presence of 30 m*M* nicotinamide, 0·4 m*M* potassium cyanide, 1 m*M* ethylenediamine tetraacetate, 50 m*M* ammonium chloride, 0·5 m*M* α-oxoglutarate, 0·01 per cent 'Triton *X*-100' and 20 m*M* potassium phosphate *p*H 7·5.

When the intact mitochondrial suspensions were irradiated, no change in the total glutamic dehydrogenase activity could be found with doses up to 133,000 r. and no significant activity could be found in the supernatants from centrifuged irradiated and non-irradiated mitochondria.

Mitochondria were osmotically disrupted in 0·025 *M* sucrose[6]; in this instance approximately half the activity was to be found in the supernatant following centrifugation at 500,000 $g \times$ min. As shown in Table 1, irradiation of the mitochondrial suspension reduced the supernatant activity considerably while the activity of intramitochondrial enzyme was relatively undiminished.

A purified, crystalline preparation of beef liver glutamic dehydrogenase (2·5 μgm./ml.) was added to a suspension of intact mitochondria and the mixture irradiated. As shown in Table 2, the activity of the free added enzyme was markedly diminished while that of the mitochondrial enzyme was unchanged. However, the presence of the mitochondria did afford some protection to the added enzyme since irradiation of the pure enzyme in sucrose alone reduced the activity to 11 per cent with 32,000 r. instead of 76,000 r. as shown in Table 2.

The results demonstrate that glutamic dehydrogenase contained within the mitochondrial matrix is remarkably well protected from the destructive effects of ionizing radiation. Equally active extramitochondrial enzyme is not nearly as well protected and is 90 per cent inactivated by a dose 2·5–5 times that required to inactivate a pure sucrose solution of the enzyme to the same degree. The specific radioprotective property of the matrix presumably derives from the presence of bound and unbound scavenger molecules, the high local concentration of enzyme and, perhaps, from the contiguous membranous structure. In addition, there is no evidence that X-irradiation of the mitochondrion leads to leakage of glutamic dehydrogenase from the matrix, even at high doses. This failure of irradiation to alter the permeability of mitochondria to this enzyme has been reported recently at lower dosage (9,000 r.) (ref. 7) and is here confirmed.

BIOLOGY

Occurrence of Glossopteridae Fructifications at Baralaba, Queensland, and their Evolution

A NUMBER of fructifications of the Glossopteridae occurred in shale in the roof of the Dawson Seam, Baralaba Colliery, Baralaba, near Rockhampton, Queensland. The specimens examined form part of

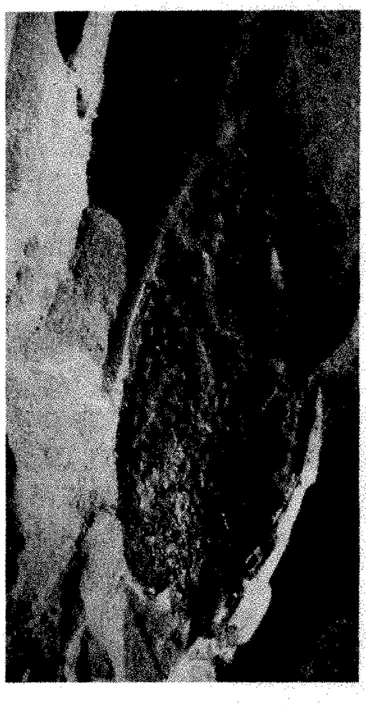

Fig. 1. *Lanceolatus* sp. attached to a leaf of *Glossopteris*. The adnate organ (upper third only is visible) does not appear to be sac-bearing, whereas the pedicellate bract-like organ appears to bear sacs. This latter organ is attached by a short, thick pedicel visible at the bottom of the photo. The leaf has taeniopteroid venation, and appears to be either *G. indica* or a very narrow *G. communis*. (× *c*. 2·7)

a collection belonging to the Geology Department, University of Queensland. The collection was made first of all by Miss B. Houston (now of the Mines Department, Queensland) and later supplemented by specimens collected by the colliery manager.

The fructifications were all unwinged, that is, of the *Cistella* and *Lanceolatus* types. They occurred as carbonaceous compressions. Unfortunately the carbonaceous material was dissected by a large number of fine parallel fractures simulating a microcleat, but it has been possible to prepare balsam transfers.

From the transfers one can see that the sacs must have represented quite a thickness of tissue as they are up to 0·4 mm. thick, but neither spores, nor pollen, nor seeds have been detected.

The nature of the probable ♀ fructification agreed with those illustrated elsewhere[1-4]. They consisted of a body bearing swollen sacs. These sacs sometimes had a rounded, convex top and at other times the top had a central circular depression with a raised central boss[1-3,5]. The latter appeared to be more mature sacs than the former. There appeared to be more 'exploded' sacs towards the base.

The only attached specimen is illustrated in Fig. 1 below. In some detached fructifications, the sacs appeared elongated, as much as three times as long as their diameter and free from adjacent sacs. The row of sacs around the margin (referred to as 'marginal sacs') appeared larger than those away from the margin (the 'body sacs'). Both marginal and body sacs showed rounding, then formation of the central depression. Plumstead's illustrations[3] of various *Cistella* species show these two types of sac clearly.

A transfer of a sac-bearing organ showed the sacs on both surfaces. Those on the reverse surface may have represented only the reflexion of the additional tissue being compressed from the obverse surface. Alternatively, it may have been derived from compression of a circular body similar to that illustrated by Sen (ref. 4, Fig. 5). There is no evidence to suggest a preference for either. Plumstead's interpretation of the nature of the fructification[2,3,6] is logical, even though largely unsubstantiated by lack of suitable material. Sen[4] and myself have both had carbonaceous material, but so far have been unable to find any definite clue to the identity of these organs.

The evidence from the Baralaba specimens supports the conclusions of Plumstead; but it is hoped with further work to be able to elucidate the true nature of these fructifications.

Based on fructifications seen by me of *Cistella* and *Lanceolatus* species from Baralaba, *Scutum thomasii* from Mt. Kembla, New South Wales[7], and *Hirsutum* sp. from the same district, along with published illustrations of fructifications[1-6], a possible line of evolutionary descent is suggested in Fig. 2 based on sac-bearing glossopterid fructifications.

The probable fructification, *Arberia*[8,9], appears ovuliferous and could have been an intermediate stage between the primeval fructification and *Ottokaria*. Particularly *A. minasica* White resembles *Ottokaria*.

Derbyella from Brazil[10] appeared to have borne spores in a manner similar to the scale leaves of *Glossopteris* first reported by Arber[11] and later reported by many others. No suggestion can be made along this line of descent.

Melville[12] has advanced an interesting theory regarding the development of the angiosperm flower. In this, the fructification of *Glossopteris* was a logical intermediary between a primitive fructification having single epiphyllous sporangia borne alternately and an inflorescence such as *Gnetum*. *Arberia* appeared a logical immediate progenitor of the *Glossopteris* fructifications if viewed in this light, although possibly removed from the main line as proposed here.

I thank Prof. Dorothy Hill, University of Queensland, for allowing me to examine the Baralaba collection; Dr. H. K. Worner, director of research, Broken Hill Pty., Central Research Laboratories, Shortland, New South Wales, for assistance; Mr. S. Thompson, of the same organization, for the photograph; and Prof. T. M. Harris, Univer-

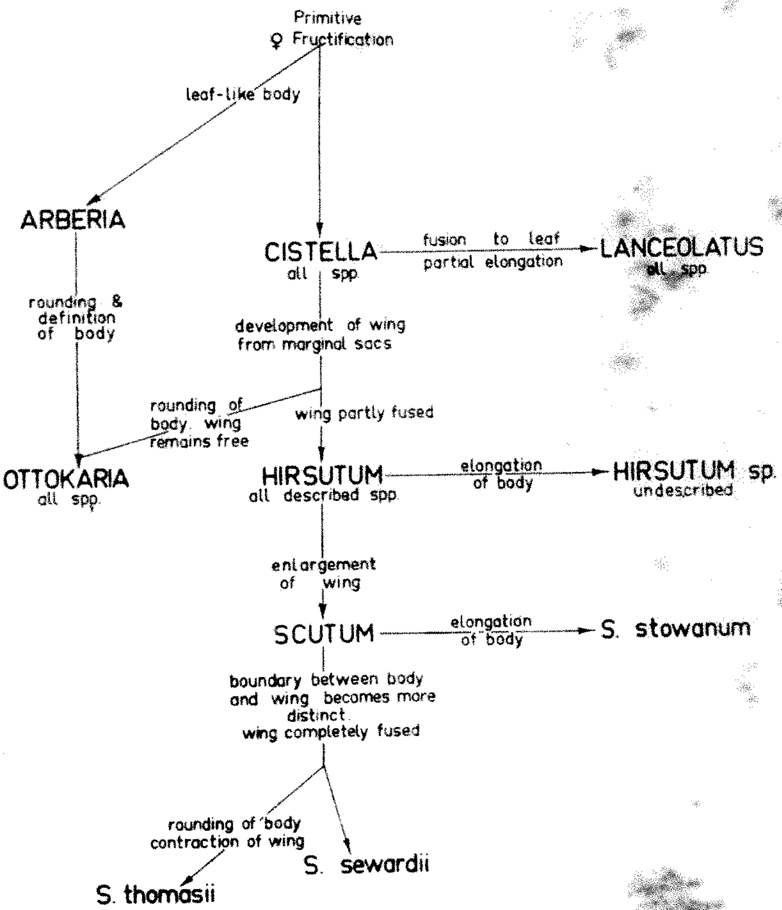

Fig. 2. Evolution of the sac-bearing organ in the Glossopteridae. Alternative lines of descent include: (*a*) primitive organ → *Arberia* → *Ottokaria* → *Cistella*; and (*b*) primitive organ → *Arberia* → *Ottokaria* and *Cistella*

A Membrane Peculiar to the Egg in the Gametophyte of *Pteridium aquilinum*

Investigations of the ultrastructure of the cells taking part in oogenesis in *Pteridium aquilinum* have shown that the mature egg possesses a membrane lying between the plasmalemma and the cellulose wall, and not present in adjacent cells (Fig. 1). After fixation in potassium permanganate and staining with uranyl acetate this additional membrane is electron dense, and it probably therefore consists of lipid or lipo-protein. The membrane is absent from the young egg and the cells preceding it, and there is evidence, which will be presented in detail elsewhere, that the material of which it is composed is derived from organelles which have degenerated during the maturation of the egg.

Although this membrane cannot be seen in sectioned material with the light microscope, DeMaggio[1] recently reports that the egg of *Todea barbara*, which unlike the egg of *Pteridium* can be viewed as a solid object lying in the venter of the archegonium, is enclosed in a thin transparent membrane. It seems likely that this membrane is similar in nature to that now detected in *Pteridium*, and such a membrane may be general in the egg cells of ferns, and possibly of other plants.

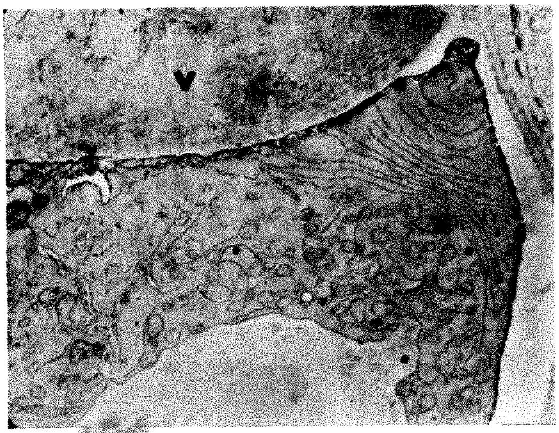

Fig. 1. *Pteridium aquilinum*. Section of mature egg stained with uranyl acetate. A densely staining membrane surrounds the egg. The egg is surmounted by the degenerating ventral canal cell (*v*). (× *c*. 5,630)

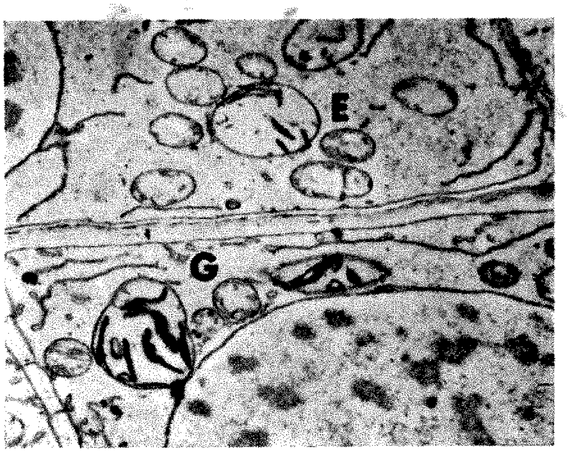

Fig. 2. *Pteridium aquilinum*. Section of portion of embryo about 15 days old and adjoining gametophyte, stained with uranyl acetate. Patches of the membrane formerly surrounding the egg can be seen lying between the plasmalemma of the embryo cell (*E*) and the cellulose wall forming the boundary between the embryo and the gametophyte (*G*). (× *c*. 10,670)

Sections of embryos of *Pteridium* show that this extra membrane persists during their early development as a layer on the inside of the outer walls of the peripheral cells. As the embryo expands and these cells divide the layer becomes attenuated and eventually discontinuous (Fig. 2).

A layer of this kind would be expected to influence the permeability of the boundary of the egg and young embryo. The failure of nucleotides to diffuse freely into the embryos of *Pteridium*, reported by Bell[2], is probably explained by its presence. Conversely the layer might also reduce the tendency of metabolites to diffuse out of the zygote and young embryo. This may explain the fact that according to DeMaggio and Wetmore[3] the isolated zygote of *Todea barbara* undergoes normal development in liquid culture up to the octant stage, but not afterwards. The irregular development which then ensures could be partly a consequence of the attenuation of the lipid layer in the outer cells of the embryo and a rapid loss by diffusion into the medium of metabolites essential for ordered growth.

Source of Dichromatism in Two Maldanid Polychætes

The tubiculous Maldanid polychætes are among the most abundant infaunal components of intertidal and sub-tidal bottom communities of the North American Atlantic coast. Within their respective ranges the two species *Clymenella torquata* Leidy and *Axiothella mucosa* Andrews show a striking dichromatism: populations may be either green or orange.

Table 1. COLOUR OF GEOGRAPHICALLY SEPARATE POPULATIONS OF MALDANID POLYCHÆTES

Species	Source	Latitude	Colour
Clymenella torquata	Passamaquoddy Bay, New Brunswick	45° N.	Orange
	Western Bay, Maine	44° 30′ N.	Orange
	Vineyard Sound, Mass.	41° 30′ N.	Both
	Long Island Sound, Conn.	41° 15′ N.	Orange
	Isle of Wight Bay, Maryland	38° 20′ N.	Orange
	Newport River, North Carolina	34° 40′ N.	Green
	Summer River, Florida	29° 50′ N.	Green
Axiothella mucosa	Newport River, North Carolina	34° 40′ N.	Green
	Summer River, Florida	29° 50′ N.	Orange
	*Alligator Harbour, Florida	29° N.	Green
Euclymene collaris	Western Bay, Maine	44° 30′ N.	Orange
	Vineyard Sound, Mass.	41° 30′ N.	Orange
	Newport River, North Carolina	34° 40′ N.	Orange

*Specimens from the coast of the Gulf of Mexico obtained through the courtesy of Dr. Alan J. Kohn, Department of Biology, Florida State University, Tallahassee.

A population inhabiting a particular microgeographic area is always consistent, although the distance over which a colour change occurs may be only a few miles. Continuous intergraduations do not occur. A third closely related species, *Euclymene collaris* Claparède, does not undergo the colour change; it exists only in the orange form even where it is sympatric with the green forms of the first two. Table 1 lists the colour of populations found at each of seven macrogeographical locations sampled by me.

The green coloration of the so-designated populations appears to be due to the accumulation of the bile pigment mesobiliverdin in the epidermal tissues of the body-wall. In the absence of mesobiliverdin the tissues derive their colour solely from yellow-orange pigments, probably carotenoids.

Individuals of all three species taken from the Newport River, North Carolina, were first placed in a 5 per cent mixture of acetic acid and ethyl alcohol. The yellow-orange extract failed to give the characteristic Gmelin reaction of bile pigments, and produced an indeterminate spectrum. The green pigment was then readily extracted from *C. torquata* and *A. mucosa* into a 5 per cent mixture of hydrochloric acid and methyl alcohol. The resulting blue-green solution elicited a distinct Gmelin reaction. Its absorption maxima at 358 and 670 mμ (Beckman *DK–2* spectrophotometer) lie extremely close to those of mesobiliverdin in hydrochloric acid: methyl alcohol (363 and 670 mμ)[1]. The solution was then diluted with an equal volume of water and extracted with chloroform. The yellow-brown hypophase was discarded, and the blue-green epiphase lyophilized and redissolved in dry methanol. The methanol solution showed fluorescence in long-wave ultra-violet light, and gave a positive zinc bilipurpurin test with an absorption maximum at 625 mμ. Following evaporation *in vacuo*, the pigment was resistant to destruction with concentrated sulphuric acid. The latter two tests confirm the presence of ethyl rather than vinyl side-chains, thus distinguishing mesobiliverdin from the related proto-compound. The initial procedure was repeated on *Eu. collaris* and orange individuals of *C. torquata* from Long Island Sound, but all attempts to extract a bile pigment of any kind were unsuccessful.

The occurrence of mesobiliverdin in animals was thought to be restricted to a few of the phytophagous insects[2] until Dales[3] recently obtained it from the terebellid polychæte *Eupolymnia heterobranchia* Johnson of the North American Pacific coast. The possibility of an analogous dichromatism within this species was mentioned, although the orange form was evidently not available for direct examination.

The most probable explanation of the observed dichromatism would attribute such sporadic accumulation of the pigment to properties of the available food in sediments inhabited by different populations. Maldanids of the sub-family Euclymeninae obtain their food by ingesting sand grains at approximately 20 cm. depth below the water-substratum interface, the lower end of their vertical tubes. Organic matter clinging to the sand particle surfaces is digested, and the particles defæcated into the water at the upper end of the tube. Since mesobiliverdin is related to a chromophoric group of phycocyanin[4], it is suggested that the colour of the polychæte reflects the density of suitable algal food organisms in the sediment. It is not known that the diet of green populations includes living algæ taken at that depth; it may consist of detrital pigment.

The complete absence of mesobiliverdin in *Eu. collaris*, which obtains its food in the same manner, indicates a subtle diversification either in the feeding processes or the digestive metabolism of these closely related sympatric species. It would be most enlightening to know whether the pigment undergoes further breakdown in the metabolism of *Eu. collaris*, or whether the animal simply returns the pigment intact to the sediment.

This investigation was aided by a research grant from the National Science Foundation (*G*.17862), L. M. Passano, principal investigator.

Promotion of Germination of *Striga asiatica* Seed by Coumarin Derivatives and Effects on Seedling Development

OUR efforts to isolate and characterize the *Striga* germination stimulant in root exudates of maize were accompanied by testing more than 270 compounds for their capacity to stimulate germination. A previous paper[1] reported the stimulation of *Striga asiatica* (witchweed) seed germination and described morphogenic effects on the seedlings induced by kinetin and certain other 6-(substituted) purines. This communication reports the results obtained with 41 coumarin derivatives, two of which stimulated germination of witchweed seeds.

Williams[2] confirmed the morphogenic effects of kinetin on young seedlings and further reported a resemblance of the effects of kinetin and red light. He suggested that since the production of shoots and the branching of roots were stimulated by kinetin and gibberellin, the development of the parasite might depend on a supply of growth factors of this type from the host. Williams also stated that the concentration of the compound required to stimulate germination appeared to be considerably less than that required to cause morphogenic changes.

Coumarin and certain of its derivatives have been reported to inhibit and stimulate plant growth processes, but coumarin has usually been regarded as an inhibitor. Neumann[3], however, has shown an auxin-like action of coumarin in promoting elongation of *Helianthus* hypocotyls, oat coleoptiles, and bean hypocotyls. He suggested that coumarin should be regarded as a naturally occurring growth regulator. Ishikawa[4] reported a stimulation of germination of *Setaria italica* seed by a 0·1 p.p.m. coumarin solution. Scopoletin (6-methoxy-7-hydroxycoumarin) has been shown to inhibit growth of oat roots at a concentration of 10^{-5} M (ref. 5), and to promote growth of pea roots at a 1 p.p.m. concentration[6].

Preparation of witchweed seeds for testing and techniques of the assay used in the present work were the same as those given in the previous paper[1]. Most of the compounds reported were dissolved in distilled water. If a compound appeared not to be water-soluble, the initial stock mixture was shaken under hot tap water and the resulting solution used in making the dilutions.

Results obtained with the two active compounds, scopoletin and 4-hydroxycoumarin, are given in Table 1. The concentrations shown include those most effective in stimulating germination.

Table 1. STIMULATION OF *Striga asiatica* SEED GERMINATION BY TWO COUMARIN DERIVATIVES

	Mean germination* (per cent) at indicated concentrations (p.p.m.)							
Compound	80	40	20	10	8	5	2·5	1·25
6-Methoxy-7-hydroxy-coumarin (scopoletin)†	10	23	34	34	29	15	5	2

† Purchased from Delta Chemical Works, Inc., 23 West 60th Street, New York 23.

‡ Supplied by Amchem Products, Inc., Ambler, Pa.

Of the coumarin derivatives considered in this study having substituent groups on the lactone portion of the molecule, only the 4-hydroxy substitution gave an active compound. 3-carbethoxy-, 3-carboxy-, 3-chloro-, 3-*p*-chlorophenyl-, 3-ethylcarboxy-, 3-methylcarboxy-, 3-methoxy-, and 4-methyl-coumarin were inactive. Substitution at the 3-position apparently nullified the stimulatory effect of the 4-hydroxy constituent since 3-acetamido-, 3-amino-, 3-carbethoxy-, 3-carboxy-, 3-ethylcarboxy-, 3-ethyl-, and 3-phenyl-4-hydroxycoumarin were inactive.

No conclusions were drawn concerning structural requirements for activity on the phenyl portion of the molecule, since only a limited number of these compounds were tested. Two naturally occurring inactive coumarin derivatives were umbelliferone (7-hydroxycoumarin) and β-methylumbelliferone (4-methyl-7-hydroxycoumarin). Other inactive compounds were: 4-amino-7-hydroxy-, 4-amino-7-hydroxy-3-phenyl-, 3-carboxy-7-hydroxy-, 3-carboxy-6-methoxy-, 3-carboxy-8-methoxy-, 3-carboxy-7-propoxy-, 3-cyano-6-methoxy-, 3-ethylcarboxy-7-hydroxy-, 3-ethylcarboxy-7-methoxy-, 6-β-glucoxy-7-hydroxy-, 6-methyl-, and 4-methyl-6-hydroxy-coumarin. Coumarin; 3,3′-*p*-chlorobenzylidine-bis-(4,7-dihydroxycoumarin); 2,7-dihydroxy-4-iminobenzopyran; 5,7-dihydroxy-4-methylcoumarin; 3-ethylcarboxy-6,7-dihydroxycoumarin; *N*-(2′-hydroxyethyl)-7-hydroxycoumarin-4-acetamide ethanol; 3,3′-methylene-bis-(4-hydroxycoumarin); methylene-bis-(4-propionoxy-3-coumarin); 8-piperidinomethyl-7-hydroxy-4-methylcoumarin hydrochloride; and 3,3′-thio-bis-(4-hydroxycoumarin) were also inactive.

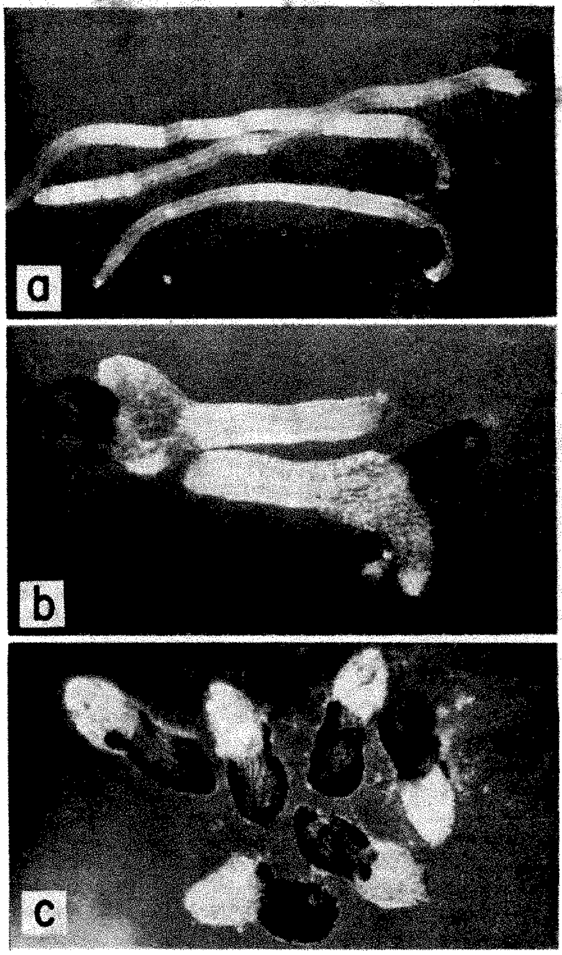

Fig. 1. *Striga asiatica* seedlings stimulated to germinate by, and left in, contact with: *a*, 2·5 p.p.m. scopoletin solution for three days. Radicles were similar in appearance to those developed in the presence of the natural stimulant (× *c*. 33); *b*, 10 p.p.m. scopoletin solution for four days. Radicle elongation has been somewhat inhibited and branching has occurred (× *c*. 67); *c*, 80 p.p.m. scopoletin solution for five days. Radicle elongation has been greatly inhibited (× *c*. 67)

The radicles of seeds stimulated to germinate by scopoletin solutions of 5 p.p.m. or lower and by 4-hydroxycoumarin at all concentrations were similar in appearance to radicles of seeds stimulated to germinate by the natural stimulant. The seedlings shown in Fig. 1*a* were floated on a 2·5 p.p.m. scopoletin solution for three days. This concentration of scopoletin appeared to promote greater elongation of the radicles than did the natural stimulant. All active concentrations of 4-hydroxycoumarin appeared to stimulate elongation.

Concentrations of scopoletin of 8, 10, and 20 p.p.m. inhibited elongation of the radicle and resulted in branching of the radicles. These morphogenic effects are shown in Fig. 1*b*. Almost no elongation of radicles occurred in scopoletin solutions above 20 p.p.m. Seeds germinating in these solutions had the short, thickened radicles shown in Fig. 1c.

No development of cotyledons, shoots, or root hairs was noted on seedlings stimulated to germinate by either of the two active coumarin derivatives.

In view of the results reported in this paper the morphogenic effects reported by Williams on parasite radicles growing in close proximity to a host root could also be attributed to a coumarin derivative instead of a kinetin-like compound. Stimulation of cotyledon enlargement and shoot growth, however, might still depend on a supply of kinetin-like growth factors from the host.

From the reports cited by Börner[7] of liberation of scopoletin and related compounds from plant roots and the finding of Brown *et al.*[8] that the *Striga* germination factor was a root-extension stimulator, the possibility that a coumarin derivative is the naturally occurring germination stimulant cannot be overlooked.

Additional indications obtained from work on the chemical nature of the natural stimulant from maize roots (to be published elsewhere) further suggest that it might be a coumarin derivative. Neither of the two active compounds reported here, however, is believed to be present in the natural stimulant. The natural stimulant appeared to be effective at much lower concentrations than were these two compounds, and Goodwin and Taves[9] reported that most naturally occurring coumarin derivatives isolated appeared not to have substitutions in the four-position. Sunderland[10], however, has recently indicated that the *Striga* stimulant from maize roots may be a complex of substances. Conceivably a coumarin compound could be one of the constituents, possibly the main constituent.

Production of Fusion Organs by the Species of *Phytophthora* which causes Foot Rot of *Piper nigrum* L. in Sarawak

A SERIOUS root disease of black pepper (*Piper nigrum* L.) was reported to be present in Sarawak by Robertson[1] in 1955. Holliday and Mowat[2] discovered that the causal organism was a species of *Phytophthora* and suggested the name 'foot rot'. In their communication it was stated that they had been unable to find the oospores of the fungus.

In July 1961, the majority of 31 cultures, remaining from a total of 81 isolates from black pepper, were found to be producing oospores after 2–4 months in pure culture on oatmeal agar. A description of the fusion organs (from isolate 78) of this *Phytophthora* species follows.

Oogonia are terminal or lateral, globose, thin-walled and hyaline when young but become thick-walled and amber to golden brown when mature; their diameter is 26–45μ (mean 35μ); the wall is smooth, or occasionally rough, 1·8–7·5μ thick (mean 3·8μ). Antheridia are terminal or lateral, thin-walled, hyaline and amphigynous; 11–15 × 11–23μ (mean 13 × 15μ). Oospores are spherical, thin-walled and hyaline when young but become thick-walled and amber to golden brown when mature; their diameter is 19–38μ (mean 26μ); the wall is smooth, 1·8–5·6μ thick (mean 3·2μ).

The identity of the species is still uncertain. Muller[3] named a species of *Phytophthora* causing foot rot of black pepper in Indonesia, *P. palmivora* var. *piperis*. Isolates from *Piper betle* L. have been referred to as *P. parasitica* Dast., by McRae[4], and *P. colocasiae* Rac., by Thompson[5], while Dastur[6] gave the name *P. parasitica* var. *piperina* to isolates from *Piper betle* and *Piper longum* L. It is thus obvious that further work is required before the Sarawak species can be finally identified.

I thank the Director of Agriculture for permission to publish this communication. The work on foot rot, initiated by the Sarawak Government, is continuing.

MICROBIOLOGY

Production of Vitamin B_{12} and Vitamin B_{12} Analogues by Pure Cultures of Ruminal Bacteria

MICROBIAL fermentation in the rumen was early recognized as the primary source of vitamin B_{12} for the cow[1]. Rumen contents contain not only the vitamin itself but also certain analogues in which the nucleotide portion of the vitamin is missing or modified by the substitution of a different benzimidazole or a purine for the base (5 : 6-dimethylbenzimidazole). In general, the analogues containing nucleotides with benzimidazole derivatives tend to possess some vitamin activity for animals while those containing purines tend to have activity only for micro-organisms[2]. The relative activities vary with different micro-organisms and even with the particular assay technique used[3]. In rumen contents, vitamin B_{12} itself makes up about 10 per cent of the activity for *Escherichia coli*, factor *A* (containing 2-methyl adenine) composes about 60 per cent, while pseudovitamin B_{12} (containing adenine), factor *B* (containing no nucleotide) and factor *C* (containing guanine) account for most of the remainder[4]. Relatively little work has been reported in regard to the part played in the synthesis of these compounds by the individual species of micro-organisms obtained from the rumen and in general such studies have not included true or functional rumen organisms[5].

In the present work, the synthetic capability of 48 strains representing 21 different species of functional rumen micro-organisms have been tested for the production of vitamin B_{12} and vitamin B_{12} analogues. These included representatives of most of the important genera isolated from the rumen of the cow[6]. The growth medium for these organisms was that of Bryant and Robinson[7] except that 20 per cent (v/v) of rumen fluid clarified by centrifugation replaced vitamins, sodium monosulphide and salts of volatile fatty acids; glucose replaced cellobiose except for the ruminococci; and the casein hydrolysate was not treated with 'Norit'. A 10-ml. culture was incubated until maximum growth was obtained, its *p*H adjusted to 4·8–5·0 and a small amount of potassium cyanide added. The sample was heated in a steam oven for 40 min. and then refrigerated until tested. All samples were assayed with *E. coli* mutant 113–3 (Davis), using the cup-plate assay technique of Harrison *et al.*[8] with their medium or that of Burkholder[9] as modified by Ford and Holdsworth[10]. Active samples were further tested with *E. coli* by the tube test of Burkholder[9] and with *Ochromonas malhamensis* (A.T.C.C. 11532) by the assay of Ford[11] as modified by Lichtenstein *et al.*[12]. All assay values were corrected for the vitamin B_{12} activity of the control medium, which contained an average of 0·45 mμgm./ml. by the cup-plate technique, 0·16 mμgm./ml. by the tube test and 0·05 mμgm./ml. by the Ochromonas assay.

* Standard error. † No. of assays.

The organisms tested by the cup-plate assay consisted of the following species and strains: *Bacteroides ruminicola* (23, $B_1$18, *GA*20, 118*B*, *GA*33, *GA*103), *Bacteroides succinogenes* (44, *S*85), *Borrelia* sp. ($B_2$5), *Butyrivibrio fibrisolvens* (49, 2–2, 3–4, *A*38, *D*1), *Eubacterium ruminantium* (*B*4, B_1C23, *GA*195), *Eubacterium* sp. (*B*17), *Lachnospira multiparus* (40, *D*32), anaerobic lactobacilli (*GA*1, *GA*19), *Peptostreptococcus elsdenii* (*B*159, *T*81), *Propionibacterium acnes* (*CL*1–2), *Ruminococcus albus* (7, 20, *B*199, $B_3$37, *D*89), *Ruminococcus flavefaciens* ($B_1$46, *C*94, *FD*1), *Selenomonas ruminantium* (*GA*192, *GA*31, *HD*4, *PC*18), *Succinivibrio dextrinosolven* (24), *Succinimonas amylolytica* ($B_2$4), *Streptococcus bovis* (*FD*10), an unnamed group, *B* 385-like (*B*385–1, 2–33, 3–18, 5–4), and 4 strains of unidentified anaerobic, motile, lancet-shaped, Gram-negative organisms. (For characteristics of these organisms, see review by Bryant[6].) Of the foregoing, only 8 strains representing 4 different species gave evidence of appreciable synthesis of the vitamin or its analogues. Results obtained with the active strains are shown in Table 1. Of these four species, *S. ruminantium* produced the largest amounts and all strains tested were active. Both strains of *P. elsdenii* tested yielded somewhat smaller amounts, while one strain each of *B. fibrisolvens* and of the unnamed *B*385-like group synthesized appreciable amounts. *S. ruminantium* and *P. elsdenii* resemble each other in that both ferment lactate and both produce propionic acid. Vitamin B_{12} is known to form part of a coenzyme system which functions in propionate metabolism[13]. Of the two organisms, *S. ruminantium* is the more important in the rumen of the mature cow, while the other predominates in calves and under special feeding conditions.

The assays with *O. malhamensis*, which reflect true animal vitamin activity, indicate that these organisms were not in general, under these pure culture conditions, synthesizing as large a proportion of vitamin B_{12} relative to the analogues as they do in the rumen (0·3–5·6 per cent of the *E. coli* plate assay value as compared to 10 per cent). While clarified rumen fluid was added to the culture medium to simulate as nearly as possible the conditions prevailing in the rumen, such conditions could obviously not be completely obtained, since, in the latter case, the various species of micro-organisms may interact.

Activity indicated by the *E. coli* tube test was only about one-fourth to four-fifths of that shown by the plate assay. This is further evidence that much of the activity shown by the synthesizing strains in the *E. coli* plate test was due to analogues of the vitamin. Preliminary ionophoretic and chromatographic studies of some of the *Selenomonas* cultures indicate that the activity present consisted primarily of two factors, one moving faster than vitamin B_{12} on chromatography and having an ionophoretic mobility corresponding to that of factor *B* and the other moving more slowly than vitamin B_{12}, possibly being factor *A*.

Modifications of the culture medium in respect to energy sources, precursor bases and the like might be expected to change the relative amounts and nature of the vitamin and its analogues present in the culture. However, it would appear from the present study that *S. ruminantium* and *P. elsdenii* are among the chief organisms responsible for the production of vitamin B_{12} and its analogues in the cow.

Taxonomy of *Haemophilus vaginalis*

THE numerous authors who have reported the isolation of '*Haemophilus vaginalis*' from cases of vaginitis, or of non-specific urethritis in men, have not succeeded in determining its *X* and *V* requirements; thus its taxonomic position is uncertain. We have therefore examined six strains of *H. vaginalis*—two from C. D. Dukes, who with Gardner first described this species[1], and four from P. N. Edmunds[2].

It was found that these strains, inoculated on fresh blood agar[2] and incubated microærophilically with increased carbon dioxide at 37° C., grow within three days as pinpoint hæmolytic colonies of Gram-negative rods. If, however, films are made after 18–24 hr. from hæmolytic zones in which no colonies are visible, the rods are found to be Gram-positive, with an arrangement suggestive of corynebacteria.

Moreover, all six strains grow comparatively copiously on nutrient media with a high serum content. On Roux inspissated serum, single colonies reach a diameter of 5 mm. after incubation for 7 days. All strains grown on Roux serum slopes are constantly Gram-positive, the majority of rods showing well-developed polar granules and some clubbing. They are catalase-negative and do not grow on a 0·04 per cent potassium tellurite medium suitable for the growth of *C. diphtheriae*[3].

Some of these characteristics are shown, according to Bergey's *Manual of Determinative Bacteriology*[4], by *C. parvum*. Two authentic strains of this species were obtained and compared with the six cultures of '*H. vaginalis*'.

The following constant differences were found on repeated examination. *C. parvum* stains Gram-positive uniformly at all stages of growth, and is catalase-positive. Unlike '*H. vaginalis*', it ferments sorbitol, adonitol and mannose; on the other hand, '*H. vaginalis*' strains ferment maltose, dextrin and starch, which are not attacked by *C. parvum*. Both species ferment glucose, lævulose and xylose. There is therefore little doubt that these '*H. vaginalis*' strains are not identical with *C. parvum* but are a species of *Corynebacterium* not previously described, for which the name *Corynebacterium vaginale* is suggested.

GENETICS

Fertility and Chromosome Pairing in Autotetraploid Rye

IT is generally accepted that the fertility of autotetraploids depends in part on the types and distributions of chromosome associations at meiosis. On this basis selection for heritable change in the distributions of the associations should be effective in improving fertility. There is, however, little experimental evidence to confirm this[1–3]. On the contrary the evidence of Morrison[4] and of Morrison and Rajhathy[5,6] indicates that selection would be ineffective. They find no evidence either for heritable variation in the pattern of chromosome association at meiosis or for its effect on fertility.

These results are surprising. There are at least two good reasons for expecting heritable variation in the chromosome association pattern: (1) Theoretically, the types and frequencies of the associations: quadrivalent, trivalent plus univalent, bivalent pair, bivalent plus two univalents and four univalents, must depend partly on chiasma frequency[7]. (2) Chiasma frequencies are genotypically controlled[8].

That both factors are relevant and operate to control the fertility of autotetraploids is in fact established by our own investigations on rye. The results which follow here are from induced autotetraploids of two F_2 families derived from crossing three diploid inbred rye lines in pairs. Firstly, the range of chiasma frequencies found in these and other F_2 families indicates segregation of genes controlling chiasma frequencies. Secondly, when quadrivalent and univalent frequencies are plotted against the chiasma frequencies of the F_2 plants, as in Fig. 1 *A* and *B*, it will be seen that the distributions of the various chromosome configurations are dependent on the chiasma frequencies. In each case the regressions are significant. The frequencies of the other associations show exactly the same dependence on chiasma frequencies. Clearly the adjustment of chromosome association frequency is a consequence of change in

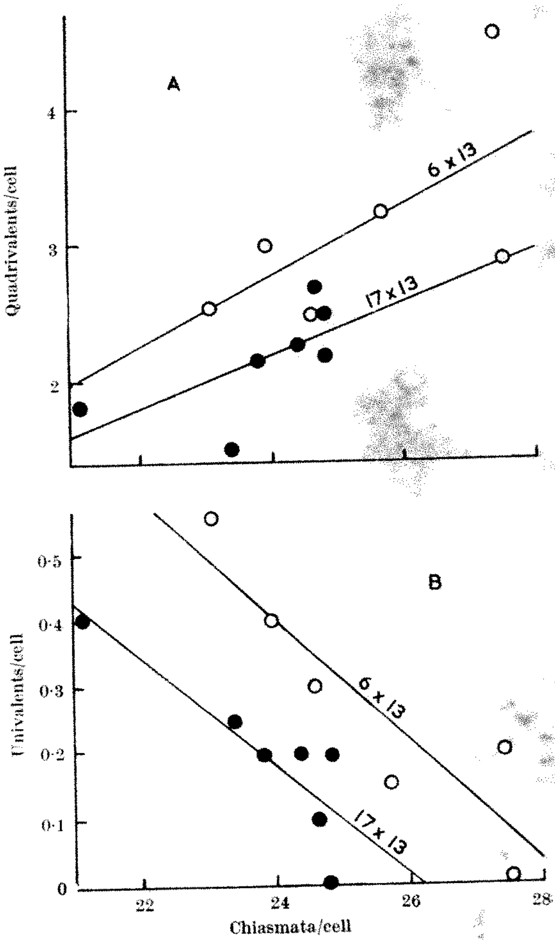

Fig. 1. Regression of association frequencies on chiasma frequencies in the two F_2 families. *A*, Quadrivalent distribution; *B*, univalent distribution calculated from the frequencies of the associations with univalents, III. I and II. 2I

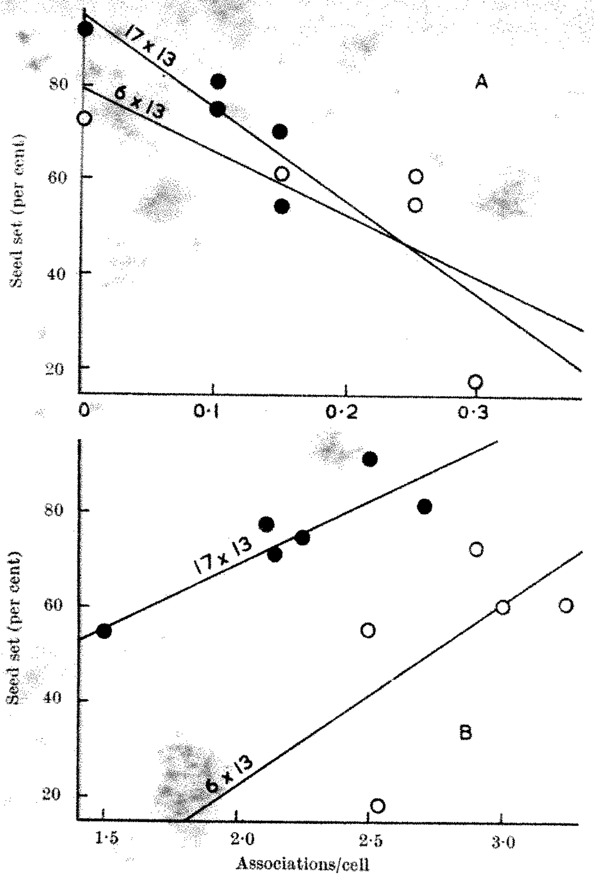

Fig. 2. Regression of fertility (percentage of seed set) on association frequencies in the two F_2 families. *A*, Trivalent frequencies; *B*, quadrivalent frequencies

chiasma frequency which, as we have inferred earlier, is genotypically controlled. It will also be observed in Fig. 1 that whereas in both F_2 families the association frequencies change with chiasma frequencies, 6 × 13, over the same range of chiasma frequencies, has more quadrivalents and more univalents than 17 × 13 ($P = 0·001$). There is, therefore, variation in the mean number of quadrivalents and univalents in the two families that is partly independent of their chiasma frequencies. This also must be assumed to be heritable, and provides an additional source of variation on which selection could act in altering the pattern of chromosome associations.

When we come to consider the relation between chromosome behaviour and fertility it is surely to be expected that variation in univalent frequency alone must influence the viability of the gametes produced. Also since many of the univalents are associated with trivalent formation a negative correlation between trivalent frequency and fertility should be expected. In Fig. 2 *A* fertility, measured as per cent seed set, is plotted against trivalent frequency. The regressions are significant and a negative correlation is confirmed. When, as in Fig. 2 *B*, the per cent seed set is plotted against quadrivalent frequency the regressions are positive.

From these results it is evident that the fertility of autotetraploid rye is dependent on the pattern of chromosome association at meiosis. Since the association pattern is under genotypic control it follows that selection for high fertility in rye must be effective and should be based on increasing the quadrivalent frequency and reducing the trivalent frequency. Both, as we have seen, would result from increasing the chiasma frequency. Finally, it is worth pointing out that the somewhat surprising relation between high quadrivalent frequency and high fertility found in rye may not hold for all other autotetraploids. In rye the chiasmata are distal and relatively few in number. This allows for efficient and regular separation of quadrivalent chromosomes at first anaphase of meiosis.

Differential Characteristics in Uniform Strains of Mice

THE pharmacological sensitivities of uniform mouse strains determined in specified conditions show clearly defined differential characteristics. The comparison is made in Fig. 1 for the same mouse strains between their approximate ED_{50} convulsive responses to doses of insulin, and their approximate LD_{50} to histamine. The colour density of the histogram is relative to the colour of the mouse strain.

The order of magnitude of these two quantal responses in any one strain of mouse is unrelated, although the *C57Br/cd* strain is the most sensitive for both. Also in each response the three white strains of mouse used resemble one another, possibly due to their derivation. The response of the *C3H* strain to insulin

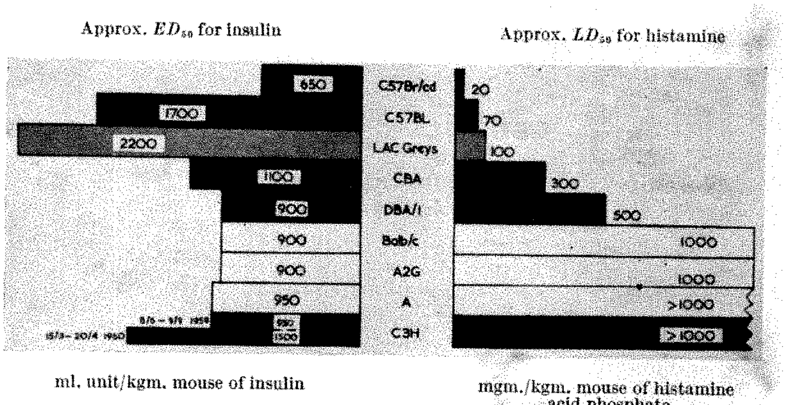

Fig. 1. Pharmacological sensitivities of some mouse strains determined in specified conditions

differed with samples of mouse, but the difference was not investigated for significance in these approximate determinations.

A further investigation of the quantal response to insulin was made with some of these strains and their F_1 crosses, and of their quantitative response to pentobarbitone sodium[1].

The results with the quantal response emphasized the genetic relation of the strains of mouse, as a species (*Mus musculus*), although specific differences were apparent between them. Of the two F_1 strains from *CBA* and *A2G* mice, the response by each more closely resembled that by its maternal parent, while the response of the hybrid from *A2G* females and *DBA*/1 males was well away from that of either parent and much less precise.

The study of the quantitative response to pentobarbitone sodium defined the necessity for using mice of the same age and sex when investigating strain differences. It also revealed that the precision of their response was distributed haphazardly between inbred and hybrid strains.

Interactions of *S* Alleles in Diploid Pollen

SELF-INCOMPATIBILITY (*S*) alleles in the pollen of autotetraploids show either independent action or one or other of two types of interaction—'dominance' and 'competition'. While dominance interaction is common, competitive interaction is rare. When two *S* alleles compete for a presumably limited amount of substrate, a competitive interaction occurs which leads to self-compatibility owing to the lack of full expression of either of the *S* alleles[1]. A theory is proposed to explain the physiology of the different types of *S* allele behaviour in autotetraploids.

Studies in the diploid pollen of *Œnothera organensis*[1] and *Trifolium pratense*[2] have shown that the same pair of alleles could show both dominance and competitive interactions in the pollen. For example, a tetraploid plant of *T. pratense* having the constitution $S_{1\cdot1\cdot3\cdot3}$ may be self-compatible because of competitive interaction in the pollen $S_{1\cdot3}$. The same pollen when applied to a style of constitution $S_{1\cdot1\cdot2\cdot2}$ may be incompatible because S_1, which is also present in the style, is dominant over S_3 in the pollen; but it may be compatible in a style of constitution $S_{2\cdot2\cdot3\cdot3}$. This situation would suggest that the occurrence of the S_1 and S_3 alleles together in the pollen does not *per se* produce competitive interaction for, if it did, $S_{1\cdot3}$ pollen would be compatible on all styles. It is evident, therefore, that competitive and dominance interactions refer to two different aspects of the incompatibility reaction.

Competitive interaction occurs only when pollen grains germinate on styles that also possess the two *S* alleles present in the pollen. Thus competitive interaction in the pollen is governed not only by its own constitution but also by the constitution of the style. Dominance interaction, by contrast, is pre-determined in the pollen and its expression is not dependent on the constitution of the style.

Specific pollen-growth substance
Specific incompatibility precursor superimposed on specific pollen-growth substance
Specific incompatibility substance superimposed on specific pollen-growth substance

Fig. 1. Interactions of *S* alleles in diploid pollen. Three units are considered essential for the full expression of an *S* allele. *A*, independent action; *B*, dominance interaction, $S_1 > S_3$; *C*, competitive interaction; *D*, dominance and competitive interaction, $S_1 > S_3$

In *Œnothera organensis* there are two units of the *S* allele complex expressed in the pollen reaction : a unit controlling the pollen-growth substance and a unit controlling the specific pollen incompatibility precursors; and the latter is believed to be superimposed on the former[3,4]. It has been suggested that in the gametophytic species the action of both these units of *S* alleles occurs post-meiotically in the individual microspores[5]. However, the conversion of the incompatibility precursors into incompatibility substances seems to occur, after germination, during the growth of the pollen tube in the style.

Dominance may occur either at the level of specific pollen-growth substance only or at both levels of the specific incompatibility precursor as well as the specific pollen-growth substance. For example, in the hybrid *Œnothera trichocalyx* (self-compatible) ♀ × *Œ. pallida* (self-incompatible), the dominance interaction occurs only at the specific pollen growth substance level[3]. It occurs at both levels in the diploid pollen of an autotetraploid of gametophytic species as well as in the typically sporophytic species[3,5]. The competitive interaction, however, may be a secondary phenomenon and occurs later in the pollen tube when the specific incompatibility precursors are converted into specific incompatibility substances and probably involves competition for the specific enzymes presumably responsible for the conversion (Fig. 1).

S alleles, being neomorphs[6], are more likely to produce physiological interaction at some stage between gene action and final phenotypic expression than most mutant alleles of ordinary genes which are hypomorphs. The former kind of alleles produce qualitatively different effects while the latter produce similar effects but of different degree. This rare property of competitive interaction within a compound locus has also been observed for the scute alleles of *Drosophila melanogaster*[7,8].

In gametophytic species when there is an independent action of alleles in the pollen the phenotypic expression is always limited to the incompatible allele[1,2,9]. A similar situation is the rule in the diploid style in which, while both alleles are fully expressed, the compatible allele does not interfere with the incompatibility reaction between a haploid grain and the style. In *Physalis ixocarpa*[9], in which incompatibility is controlled by 2 series of S alleles, when 2 alleles act independently, the occurrence of only one common allele in the pollen and the style is enough to produce incompatibility. These observations support the 'oppositional inhibition' theory[10] of physiological mechanism of incompatibility reaction.

MISCELLANEOUS

Plastic/Carbon Replication for Electron Microscopy

THE use of plastics, such as 'Bedacryl 122X' (ref. 1), 'Triafol', etc., in the preparation of carbon replicas for examination in the electron microscope is well known. A massive plastic replica is made and vacuum-coated with carbon; the plastic is dissolved in a suitable solvent, leaving a carbon replica of the surface of the original specimen. The carbon replica can be mounted on a copper grid, shadowed, and examined in the microscope.

However, the plastics tend to swell as they dissolve, occasionally causing the carbon replicas to buckle and fold over or break. This is particularly true of replicas of rough surfaces. Sometimes a coating of paraffin wax can be used to stabilize the carbon replica while the plastic is being dissolved, the wax coating being afterwards dissolved in petroleum ether. This technique can be applied to 'Triafol'/carbon replicas; methyl acetate saturated with paraffin wax is used to dissolve the 'Triafol'.

At best, however, this method is somewhat unsatisfactory. First, the wax does not adhere very well to the carbon replica and may become detached from it during dissolution of the plastic. Secondly, unless precautions are taken, evaporation of the wax-saturated solvent precipitates wax on to the plastic, which consequently is incompletely dissolved. The technique is anyway inapplicable to 'Bedacryl'/carbon replicas because of the high solubility of paraffin wax in solvents used for 'Bedacryl'.

A method free from the shortcomings of the paraffin-wax technique has been developed in this laboratory. It involves the use of gelatin (which is insoluble in most organic liquids but soluble in water), and can be used with 'Bedacryl' as well as with other plastics. The procedure recommended is as follows:

A carbon-coated plastic replica is prepared by the usual method. A thin layer of a warm, freshly prepared, 20 per cent aqueous solution of gelatin is then spread over the carbon-coated surface and allowed to dry. The plastic/carbon/gelatin film is cut into small pieces which are transferred to a bath of solvent to dissolve the plastic. During the dissolution the carbon replica adheres well to the gelatin and does not buckle. When all the plastic has dissolved, the carbon/gelatin films are removed from the bath, allowed to dry, and then floated, gelatin downwards, on the surface of a bath of warm water. After the gelatin has dissolved the replicas are picked up on grids, rinsed with water, and allowed to dry. The replicas can now be shadowed (if this has not already been done prior to carbon coating) and examined in the microscope.

By this method, clean, whole carbon replicas, large enough to cover a standard grid, can be made.

A Solvent Trough for Paper Chromatography

DR. M. D. GWYNNE has described an easily made solvent trough for use in descending paper chromatography[1].

In this laboratory we have also found the glass troughs costly, difficult to make, and easily broken. For several years we have, therefore, made troughs from commercial plastic knife-boxes. In these boxes there are compartments of different sizes for the storage of knives, spoons and forks. A compartment of suitable size is cut out as shown in Fig. 1 (top). Two glass rods of suitable length are held together by means of two plastic pieces also cut out of the knife-box (Fig. 1).

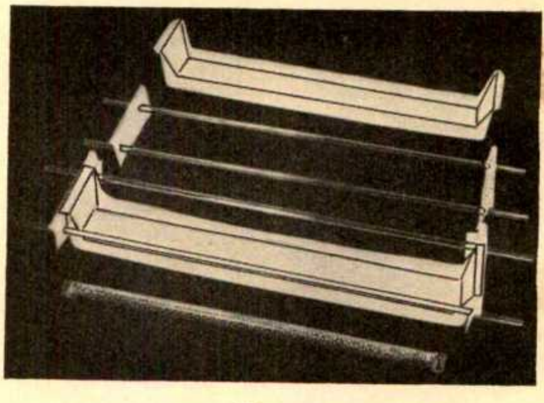

Fig. 1

When the trough is to be used, it is held between these two plastic parts (Fig. 1, bottom). The detail in the foreground of the illustration is a glass tube, filled with lead shot and sealed in both ends. It is used for keeping the papers in position when the trough is used.

FORTHCOMING EVENTS

Tuesday, July 17—Thursday, July 19

Society for Applied Bacteriology (at the School of Agriculture, Sutton Bonington, Loughborough, Leics.)—Summer Conference.

Thursday, July 19

Royal Society of Tropical Medicine and Hygiene (at the Hospital for Tropical Diseases, St. Pancras Way, London, N.W.1), at 7.30 p.m.—Clinical Meeting. Chairman: Sir George McRobert.

Friday, July 20

Nutrition Society (at the Central Veterinary Laboratory of the Ministry of Agriculture, Fisheries and Food, New Haw, Weybridge, Surrey)—Symposium on "The Effect of Changes in Nutrition on the Host-Parasite Relationship".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Librarian—The Registrar, The University of York, The King's Manor, York (July 20).

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Sheffield (July 20).

Demonstrators (with good honours degrees and approximately one year's research experience) in Chemistry—The Registrar, University College of Wales, Aberystwyth (July 21).

Junior Research Fellow (with a good honours degree, or equivalent, in chemistry, biochemistry or agricultural chemistry) in the Department of Soil Science, for chemical studies on changes in forest litter resulting from nitrogen fertilizer treatments—The Secretary, The University, Aberdeen (July 21).

Lecturer (with research experience in experimental nuclear physics) in Physics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (July 22).

Assistant Lecturer in Applied Mathematics—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (July 23).

Assistant Lecturer (with a good honours degree in zoology and preferably a special interest in genetics) in Zoology—The Registrar, King's College (University of London), Strand, London, W.C.2 (July 23).

Assistant Lecturer (with a good honours degree in botany) in Botany—The Registrar, King's College (University of London), Strand, London, W.C.2 (July 23).

Junior Research Fellow (with a first- or second-class honours degree in chemistry or biochemistry, or equivalent qualification, plus at least two years postgraduate experience, preferably in a field involving biochemistry), to work under a microbiologist on the problem of chemical compounds associated with the development of mould growth on oilseeds and related foodstuffs, including the biochemical aspects of the investigation—Tropical Products Institute, D.S.I.R., 56–62 Gray's Inn Road, London, W.C.1, quoting Ref. YE.728/2 (July 23).

Lecturer or Assistant Lecturer (preferably with experience in the field of nuclear magnetic resonance) in Inorganic Chemistry—The Registrar, The University, Leicester (July 24).

Lecturer and an Assistant Lecturer (men or women graduates) in Zoology—The Secretary to the Council, Westfield College (University of London), Kidderpore Avenue, London, N.W.3 (July 27).

Assistant Lecturer or Demonstrator in Pathology—The Registrar, The University, Manchester 13 (July 28).

Junior Research Fellow in Botany—The Registrar, The University, Sheffield (July 28).

Chair of Biochemistry; and Chair of Pharmacology in the University College, Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, Senate House, University of London, London, W.C.1 (July 30).

Senior Lecturers or Lecturers (2) in Anatomy; and a Senior Lecturer or Lecturer in Physiology at the University College, Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, Senate House, University of London, London, W.C.1 (July 30).

Evans Medical Research Fellow (with an honours degree in physiology or biochemistry) in the Nutritional Aspects of Hæmatology—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (July 31).

Lecturer in Psychology at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, July 31).

Assistant in Research (with an honours degree in engineering, agricultural engineering, or the equivalent) in Agricultural Engineering—The Secretary, School of Agriculture, The University, Cambridge (August 2).

Lecturer (with an honours or higher degree in physics, and preferably previous teaching and research experience) in Theoretical Physics at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, August 18).

Fellow (with experience of research in New Guinea in social anthropology) in the Department of Anthropology and Sociology, Institute of Advanced Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 24).

Ferranti Fellow (with the degree of Ph.D. or similar research experience) to carry out research in any field connected with electronic computing machines—The Director, University Computing Laboratory, 9 South Parks Road, Oxford (August 31).

Lecturer in Parasitology (with special reference to flatworms)—Head of the Department of Zoology, Imperial College of Science and Technology, London, S.W.7 (August 31).

Lecturer/Senior Lecturer (with experience and research interests in inorganic chemistry, and preferably with a special knowledge in the application of visible and ultra-violet absorption spectroscopy, magnetism and theoretical chemistry to co-ordination compounds of the transition metals) in Inorganic Chemistry at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 31).

Lecturer (preferably with a special interest in economic geography, particularly in regard to location theory, transport, and/or resource development) in Geography at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 15).

Arthur Jackson Chair of Human Biology and Anatomy—The Registrar, The University, Sheffield 10 (September 20).

Official Fellow and Tutor in Mathematics—The President, Magdalen College, Oxford (October 22).

Chemist, Biochemist or Microbiologist, to study the aspects of cellular radiobiology—The Director, Experimental Radio-pathology Research Unit, Hammersmith Hospital, Ducane Road, London, W.12.

Engineer (with Higher National Certificate or proven practical ability, and preferably a working knowledge of transistor technique) in the Statistics Department, to assist with maintenance of electronic digital computers and peripheral equipment—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Experimental Officer or Assistant Experimental Officer (with a pass degree, H.N.C., or equivalent, or, if under 22, G.C.E. "A" level or equivalent) in the Chemistry Department, to help with research on mineral metabolism in cattle, particularly the forms of combination of magnesium and calcium in cattle diets and ingesta, and the development of the analytical methods to be used—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 61/15.

Head of the Mathematics Department (Grade E)—The Headmaster, Bradford Grammar School, Bradford.

Lecturer or Senior Lecturer (with good academic qualifications, and preferably research experience to doctorate level or equivalent) in the Department of Electrical Engineering—Dr. J. H. Calderwood, Royal College of Advanced Technology, Salford.

Lecturer (preferably with interests in the mechanics of continuous media) in Applied Mathematics—Head of the Department of Mathematics, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7.

Lecturer (with experience and interest in electrical measurement, and preferably special qualifications in electronic and/or high frequency techniques) in the Department of Electrical Engineering—The Academic Registrar, Loughborough College of Technology, Loughborough, Leics., quoting Ref. 15/G.

Mathematical and Science Teachers (fully qualified) at the Imperial Ethiopian Naval College, Massawa—Cdr. I. Desta, Imperial Ethiopian Embassy, 17 Princes Gate, London, S.W.7.

Research Assistant (honours graduate in botany) in Quaternary Research—The Registrar, The University, Leicester.

Research Assistant (with experience and ability in organic chemistry), for the preparation of compounds related to bile acids for biological assay—Prof. G. A. D. Haslewood, Biochemistry and Chemistry Department, Guy's Hospital Medical School, London Bridge, London, S.E.1.

Research Fellows (2) (preferably with a Ph.D. degree in engineering or physics, or equivalent research experience) in the Department of Electrical Engineering, for work in the field of millimetre wave techniques, under Prof. A. L. Cullen—The Registrar, The University, Sheffield 10.

Senior Geologist (with a first- or good second-class honours degree in geology or engineering geology with at least seven years postgraduate experience in water supply geology, and preferably experience in electric logging of boreholes) in the Geological Survey Division of the Federal Ministry of Mines and Power, Lagos, Nigeria, for duties which will include the compilation of water supply records, the preparation of water supply papers for publication, and the supervision of water supply exploration drilling programmes—The Recruitment Attaché, Nigeria High Commission, 9 Northumberland Avenue, London, W.C.2, quoting Ref. J.4/7.

ALLOCATION OF SCIENTIFIC RESEARCH IN BRITAIN

IN January 1961, the Council of the Institution of Chemical Engineers set up an Exploratory Committee under the chairmanship of Prof P V Danckwerts to review the role of chemical engineering as applied to all manufacturing processes It was expected that one result would be the recognition of new fields for the application of chemical engineering principles and practices Specifically, the Committee was to survey selected fields and report on recent developments, trends and gaps in knowledge, assessing their chemical engineering significance, to recognize the major advances and to indicate how the deficiencies might be made good On occasion the Committee might indicate the existence of unnecessary, or duplication of, effort in chemical engineering research, and from time to time it might form *ad hoc* sub-committees as study groups for particular aspects of their work

This Exploratory Committee, the report of which was published in the April 1962 issue of *The Chemical Engineer*, covered a rather narrower field than the Committee on Chemical Engineering Research of the Department of Scientific and Industrial Research which reported early in 1951 That Committee, of which Mr H W Cremer was chairman, was appointed to review the needs for research in chemical engineering and the extent to which they could be met by existing facilities, but it also indicated a number of fields in which industry considered there was further need for chemical engineering research The main conclusion of the Cremer Committee was that national requirements for chemical engineering could only be met if existing facilities for research were supplemented by a central organization specially adapted or created for the purpose No such organization has yet emerged, and although the colleges of technology may now be able to make a more substantial contribution to research in this field, in the view of the Danckwerts Committee, requirements for research remain as stated by the Cremer Committee

The Danckwerts Committee has therefore considered the contribution which existing Government research institutions, such as the National Chemical Laboratory, the National Engineering Laboratory or the Warren Spring Laboratory, might make in this field While close contact with industry is desirable, the Committee considers that these research stations should remain free to carry out autonomous programmes of a general and fundamental nature There is much work which is unlikely to be done by industry and which is unsuitable for universities Research institutes, with their continuity of work, large technical staff, and freedom from the need to shape projects to degree requirements, are better suited than universities to make systematic measurements of chemical and physical quantities of the kind which look into chemical engineering design calculations It is suggested that consultation between industry and the universities could lead to the formulation of a worth-while programme on these lines

Besides this, the Committee points to sub-technologies which enter into a wide variety of industries, but are not studied adequately in their own right, because they do not form the primary interest of any one industry Powders and granular materials are given as one example and one for which the Warren Spring Laboratory might be appropriately used More information is also needed on heat transfer in situations of particular interest to chemical engineers It is suggested that work here on viscous and non-Newtonian fluids, condensing and multi-component vapours, and packed and fluidized beds, for example, would be a logical extension of the work of the National Engineering Laboratory on heat transfer It is also suggested that the Department of Scientific and Industrial Research could provide a valuable service to industry generally by making critical surveys of the literature of selected subjects Examples are to be seen in those on crushing and grinding and on industrial drying which have already been published, and that on solid–liquid separation which is in hand, but the point is made that such surveys should be regarded as a public service rather than as something to be sponsored by particular industries

The Danckwerts Report suggests that the Institution of Chemical Engineers should play a greater part in influencing the activities of the Department of Scientific and Industrial Research along the lines indicated Industrially sponsored projects should not be allowed to dictate the programme, and after discussion with the Secretary of the Department, the Committee recommends the establishment of a Research Committee of the Institution to formulate detailed proposals, and it would seem that what the Exploratory Committee has in mind is the formation of a Research Council such as has recently been established by the Institution of Civil Engineers in collaboration with industrial associations and the Department of Scientific and Industrial Research. In the present report the activities of the research associations are only mentioned, although the Exploratory Committee is obviously aware of their potentialities However, they are concerned with activities which seek to further the dissemination of ideas and not the raising of funds for research, stress is laid on the need for constructive thinking if satisfactory proposals for an effective organization are to be formulated

The Exploratory Committee was naturally enough concerned particularly with the possible role of the Institution of Chemical Engineers in encouraging, promoting or guiding research in chemical engineering and allied fields, the proposal for a research committee or council is only one of the recommendations of the Report. The Committee thought that there were four requirements First, to help industry to formulate and implement explicit research programmes in fields of chemical engineering in which fundamental research is needed Secondly, to help the universities and colleges of technology to maintain lively and realistic research programmes Thirdly, to suggest speculative and exploratory fields of research detached from the present-day preoccupations of industry; and fourthly, to make recommendations in the appropriate quarters as to the part which Government research institutes might play in chemical engineering

A professional institution is clearly at an advantage over industry in approaching the universities and colleges of industry in the way suggested, and the whole Report appears to be inspired by a conception of the functions of the professional institutions in the structure of research in Britain This is in striking harmony with the views which Lord Hailsham has expressed to the Parliamentary and Scientific Committee and which the Parliamentary Secretary for Science outlined in an address "A Policy for Science" to the Reading and District Council for Education in World Citizenship on May 25 The Exploratory Committee stresses the importance of giving due weight in research to the development of concepts and theories, and is considering how best the practical problems of industry can be grouped into separate fields in such a way as to prevent overlapping and to emphasize those features which are common to apparently different problems The appointment is recommended of a number of investigators, who would be called Industrial Research Fellows, to report on one specific field (see p 229 of this issue)

Each Industrial Research Fellow should endeavour to establish what are the real industrial problems, what additions to our knowledge might mitigate these problems, and what programme of fundamental research might provide the knowledge required Admittedly, these questions are difficult to answer with any precision, and it is arguable whether any one man could always be expected to provide the answers However, the Exploratory Committee cited the report of the Distillation Panel of the Association of British Chemical Manufacturers and the British Chemical Plant Manufacturers Association as an example of the degree of detail which might reasonably be expected Judgment and common sense are clearly as important as intellectual ability, and the Committee looks to the scheme to promote association with the staffs of universities and colleges of technology as well as with industry The resultant reports might serve as the primary agenda of a working party or form the basis of a co-ordinated scheme of research

The working parties visualized by the Exploratory Committee are likewise regarded as a means of bringing together those in industry, in the universities, in research associations and research institutes who are working on, or interested in, specific topics Careful thought must obviously be given to both the size and functions of any such working parties and to their relations with other bodies, though it appears to be of the essence of the scheme that the topics will represent fields which are not at present receiving attention An actual example is given in the working party on fluidization which has already grown up through the influence of a member of the Institution, Prof J F Richardson, and any such working parties are visualized as sponsored specifically by the Institution, which would appoint chairman and honorary secretaries and provide secretarial assistance and accommodation as required

This proposal for Industrial Research Fellows is designed to cover research in fields which represent established industrial activities, but the Committee recognizes that it is equally necessary that there should be speculative or exploratory research aiming ultimately at new techniques, substances, processes, inventions, design procedures, control mechanisms and such like Such research, it points out, is less likely to be inspired by the day-to-day problems of industry and is more likely to arise from an appreciation either of industrial requirements in the widest sense. or of the possibilities inherent in some phenomena or idea. Another problem of wide scope is the recognition of new fields of chemical engineering, and like speculative or exploratory research, this cannot be stimulated in such a systematic way as research directed towards the solution of present industrial problems

Here, as the Danckwerts Committee recognizes, something is being dealt with which cannot be organized It is a matter of providing the conditions which foster creative work and seeing that men of the requisite quality are given the opportunity to develop their ideas There is indeed a matter of communication and seeing that the channels for the communication of ideas are free and adequate However, on this aspect of chemical engineering research it is interesting to note that the Danckwerts Committee is not looking solely to the universities either for investigators or facilities

In a recent broadcast talk on the Third Programme, published in *The Listener* for May 3, Dr Dennis Chapman pointed out that there was already a marked trend for experimental research in the physical sciences to move away from the universities, and he thought that this trend would continue Although the actual expenditure on research in the universities had increased, relative to industry, expenditure on university research had dropped remarkably Much nuclear research that would at one time have been the sole prerogative of the universities is now also carried out, for example, at the National Physical Laboratory.

Admittedly, this trend can be attributed at least in part to the high cost of much modern equipment coupled with the fact that a university department is seldom well placed to provide the organized team with a variety of scientific talents which is so often essential for an organized attack on complex problems. Quite apart from the Government's rejection of the University Grants Committee's advice on university finance for the next quinquennium, concern has been expressed about the financing of fundamental physical research in the universities

However, Dr Chapman rightly points out that the financing of university research to-day presents a far too complex problem to be solved merely by increased funds It calls for clear thinking about the functions of the universities in regard to research and whether they should be just training centres or something much more Nor, as Dr Chapman fully recognizes, can such questions be answered without reference to what is being done elsewhere If we are satisfied that the trend away from the universities is reasonable, are we, for example, also satisfied with the quality of research carried out elsewhere ?

Dr Chapman does no more than touch on the problems involved He recognizes that industry, at least large-scale industry, is seeking to find a reasonable balance between the more fundamental type of research and the more directly applied, as well as the purely empirical, work This is true, too, of the research associations, while, as he also notes, a good deal of university research could, with every justification, be called applied research Work correctly described as applied research in one field may yield facts and conclusions that are fundamental to another, and while Government and industrial establishments are now responsible for much that can properly be termed fundamental research, it is so easy to ignore research of this type that special care must be taken to foster and protect it

Dr Chapman suggests that to counteract the deleterious effects of the present trend of research away from the universities, the universities must either modify their organization and appoint many full-time research workers, with perhaps loosely linked research institutes for advanced study, or sponsor research centres for co-operative work At the same time, research in Government and industrial laboratories requires expansion in scale and improvement in quality, and, like the Zuckerman Report, he urges greater mobility of personnel between Government, industrial and university laboratories The first suggestion obviously involves a considerable expansion in the funds at the disposal of the universities for research, and if, in fact, the ceiling imposed by the Government on university expenditure is valid for economic reasons, there may well be sound reasons why, in the national interest, the universities should allocate a larger proportion of their funds for research purposes instead of for expansion of the numbers of students The second manifestly is a matter of administration and may well be for consideration by the Treasury Committee which is reviewing the organization for the promotion of civil service by Government agencies

What seems important is that the policy suggested by the Exploratory Committee of the Institution of Chemical Engineers in regard to chemical engineering and by Dr Chapman in discussing research in transition should have so much in common with the views which both the Minister for Science and his Parliamentary Secretary have freely expressed They are in full accord with the research council philosophy, with the idea that the first task of the Government in fostering research to support first-class people with promising ideas, and to refuse to support the bogus or second-rate Administratively, the prime need is an organization headed by a Minister, capable collectively of isolating the right questions, conducting the proper discussion of them with the right people both inside and outside the Government organization, making certain that the real problems are discussed and that the scientific answers are given by those who alone are capable of giving them

It is, of course, a help for the administrator to have a knowledge of scientific principles and even some scientific training But the vital need is to ensure a proper and effective relation between the scientist and the administrator and between the two of them and the responsible Minister In this connexion, in his address on May 25, Mr Freeth stressed the fact that the Research Councils are not research monopolies The effectiveness of the present system in Britain derives largely from this fact, from its flexibility and from the care which is taken to ensure that private foundations, professional bodies and the independent research institutes have their full opportunity to contribute There may be room for discussion and examination as to the respective roles of these bodies, the universities, the colleges of technology, Government institutions, the industrial research associations and industry, and chemical engineering is probably not the only field in which arrangements for co-operation could be improved

Lord Hailsham is clearly determined to re-value thoroughly the whole Government organization The Zuckerman Report is already being used as a working document for this purpose, including some inquiry into the organization of the Scientific Civil Service Besides the inquiry into the research associations instigated last autumn, the Committee set up by the Treasury under the chairmanship of Mr B St Trend, to review the organization of civil science under Government agencies, is expected to give the Minister some guidance on the handling of radio-astronomy and large projects in nuclear physics which involve the question of university grants in the physical sciences as against the life sciences It is also hoped that this Committee will assist the tidying of the organization of science under Government generally and the removal of such apparent anomalies as the responsibility of the Admiralty for the Astronomer-Royal or of the Board of Trade for the National Research Development Corporation

The Treasury Committee's terms of reference are comprehensive and its membership, including Sir Keith Murray, Lord Todd and Prof C H Waddington, guarantees that the mechanism of advice to the Minister for Science and functions of the various agencies for civil science and their relations with other bodies will not be considered from a narrow angle Its existence indeed should encourage the Institution of Chemical Engineers and other professional institutions to proceed with any constructive proposals for strengthening Britain's organization for research The next report from the Advisory Council for Scientific Policy will be awaited with special interest.

THE ALGAE

The Algae
By Prof V J Chapman Pp viii+472 (London Macmillan and Co , Ltd , New York. St Martin's Press, Inc , 1962) 35*s* net

THE purpose of this book, which follows the general layout of the author's earlier work (1941), is to provide a survey of all aspects of the algae such as may be required by a university undergraduate, with selected parts marked for the use of schools and first-year students The author emphasizes that this work is not a second edition of his 1941 book but a new work incorporating recent advances in phycology

Some chapters—algal ecology, ecological factors and algal physiology—have been rewritten and two new chapters on the history of the algae and the economic uses of seaweeds have been added However, a large portion of this book has been taken direct from the 1941 book without any attempt to recast the text A survey of the algae is certainly given, but whether the balance the author has adopted with regard to the subject-matter will give the student a true picture of the algae is doubtful It is also debatable whether the type method of presentation that the author has used will be welcomed by the majority of university teachers

The first two-thirds of the book is devoted to morphology and taxonomy, and the introductory outline classification might, with advantage, have been a little fuller to give continuity to the rest The bulk of the morphological section is devoted to Euphycophyta (Chlorophyceae 99 pp , Phaeophyceae 93 pp , Rhodophyceae 42 pp), the Chrysophycophyta (Xanthophyceae, Bacillariophyceae, Chrysophyceae) occupying a bare 16 pages, the Pyrrophycophyta only 3 pages and the Myxophycophyta 16 pages The classes Euglenophyceae and Chloromonadophyceae are omitted from the taxonomical section although the genus *Euglena* is referred to in later sections The omission of these classes is regretted, particularly as *Euglena* is a type for many university entrance examinations also there is no certainty that filamentous (or pseudofilamentous) forms, equivalent to those in the Chrysophycophyta and Pyrrophycophyta, do not exist

The rest of the book considers fossil forms, reproduction, evolution, marine, salt-marsh and fresh-water ecology, ecological factors, physiology, symbiosis, geographical distribution, life forms and utilization In the space available this part of the book gives a considerable amount of useful information It is a pity however, that the author did not take the opportunity to incorporate into the appropriate sections the results from important recent researches, such as the work on fossil Dinophyceae and the recent studies on marine and fresh-water phytoplankton

A subject and author index is provided, and selected references for further consultation are given at the end of each section The work is profusely illustrated, and while this will be of considerable help to students, the general effect of the illustrations is very displeasing The lines are too heavy and the figures too crowded together Where figures have been redrawn they are usually inferior to those in the 1941 book and in one instance (Fig 29) the legend written for the 1941 book has not been corrected to fit the revised figure

As a result of utilizing text from the 1941 boo without any revision there are many inconsistencie in terminology which will be very confusing t students, for example, the use of Myxophyceae an Bacillariophyceae in the new parts and Cyanophycea and Diatomaceae in the text taken from the earlie book It is even more confusing when the autho uses "cilia" to mean flagella on page 9 and the sam word to mean mastigonemes (hair-like processes on flagellum) on p 259 Further, the genus *Botryococcu* is still left in the Xanthophyceae instead of bein moved to the Chlorophyceae. In addition, erroneou statements such as "the Chrysophyceae are nearly a freshwater", that "leucosin is a protinaceous substance" and that *Polysiphonia fastigiata* (*P lanosa* is "always found on one particular host, *Ascophyllum*" cannot be excused Neither can the incorrect statement (p 126) that Manton found only 9 fibrils in th posterior flagellum of the phaeophycean autherozoi be allowed to stand

We are very disappointed that the publicatio of this, the most recent algal text-book published i English, was not delayed until the whole text ha been thoroughly recast and brought into line wit modern trends Then much more of the interestin recent work could have been included in the tex and the result would have been a somewhat large but much more useful student algal text-book

CELL BIOLOGY

International Review of Cytology
Vol 9 Pp x+424 13 dollars Vol 10 Pp xiv+409 13 dollars Vol 11 Pp xxi+356 88*s* Edited by G H Bourne and Prof J F Danielli (New York Academic Press, Inc ; London Academic Press, Inc (London), Ltd , 1961)

THE sails of histology, after dominating the physiological seas in the nineteenth century and in the early years of the twentieth, fell limply into the doldrums in the period between the two World Wars But now, once again, they are filled and, indeed, fresh winds are blowing so strongly from several different directions that it becomes increasingly difficult for the cytologist to preserve his balance as his vessel veers hither and thither on new courses of discovery

In these three volumes of the *International Review of Cytology* many new approaches toward the study of cells come under expert scrutiny by investigators of many nationalities, though preponderantly from the United States Moreover, the cells may be bacterial, protozoan, annelid, arthropod, echinoderm, molluscan, piscean, amphibian, avian, mammalian or human, all come under review, and the reader must take them all in his stride He must either be a real biologist already, or become one

Naturally, all the articles are not uniformly good or interesting, for, in any event, what is interesting depends partly on the taste and idiosyncrasy of the reader For this reason it would be invidious to select particular articles on which to comment Some are almost purely chemical (for example, "The Chemistry of Schiff's Reagent"), some are embryological and functional (for example, "The Mechanism and Mechanics of Cleavage"), others are studies of detailed structure made mostly with the electron microscope (for example, "The Fine Structure of

Insect Sense Organs", or "The Electron-microscopic Analysis of Secretion") Incidentally, this last article emphasizes the difficulties of gaining any real concept of the sequence of events by studies of sectioned material only In spite of much excellent micro-cinematography of cells (see the article by C M Pomerat on "Cinematography, Indispensable Tool of Cytology") the concept that granules in cells are a necessary part of the secretory process dies hard Such activities as pinocytosis and the temporary storage of raw materials and the accumulation of metabolic by-products tend to be forgotten by many investigators of secretory processes when they are attempting to interpret the photographs of fixed sections Similarly, if the vast array of surfaces and membranes, belonging to various parts of the endoplasmic reticulum, mitochondria and the like are really the sites for the production of secretions by chemical syntheses, the final products might never accumulate anywhere, but could be dispersed molecule by molecule into the tissue-fluids, ducts or blood-stream, just as and when they were produced In a factory, storage is only necessary when production exceeds demand Fleet Street can daily saturate the breakfast tables of Britain with only the minimum of storage in the printing works

Books of the kind under review make invaluable reading for all biologists New horizons are inevitably opened up to the reader, and the exploration of uncharted seas provides stimulating competition for the old-established and perhaps obsolete trade routes Though some of the articles are more condensed than others, all are genuine reviews and not just annotated lists of references As such they should appeal to all biologists who are concerned with how things work and not only to cytologists in the narrow sense

E N WILLMER

FACT AND SURMISE ON VIRUSES

Advances in Virus Research

Vol 8 Edited by Kenneth M Smith and Max A Lauffer Pp ix + 414 (New York Academic Press, Inc , London Academic Press, Inc (London), Ltd , 1961) 86*s*

THE three main components of a science are the methods used to make observations, the observations, and the interpretations based on them The last merge smoothly into surmises, and the zone to which one label rather than the other is attached is clearly a matter of opinion In the early days of virus research there was so little genuine information that interpretation made up an unusually large proportion of the whole This seems to have established a tradition, and it is piously maintained by Kellenberger and by Mahler and Fraser in the articles on bacteriophage in this book Each contains much valuable information, and the authors, as a rule, distinguish observation from surmise but there is a risk that many readers will not keep the distinction continually in mind, in the face of such admirably persuasive presentations, and will get a false impression of the amount that is definitely known

To redress the balance there is an article by Valentine on the enhancement of contrast in electron microscopy This explains what is done, why it is done, and why alternative methods would be ineffective After a general section on photographic contrast, the merits of different methods for varying the electron-stopping power of the specimen are discussed. This is followed by a comparison of the results achieved by 'staining' viruses with heavy atoms, by surrounding them with a film containing heavy atoms so that the viruses show up in 'negative contrast', and by Muller's technique of evaporating metal across the dry preparation from one side so that the viruses and their surface features cast shadows

Cooper contributes an article on plaque assay of animal viruses A thin layer of living susceptible cells is immobilized on the wall of a suitable vessel, either by allowing the cells to become attached or by embedding them in agar, the virus suspension is then spread over the surface Plaques of infected cells develop and can be recognized either by direct observation or after staining The method is formally identical with the plaque assay of bacteriophage on a plate covered with susceptible bacteria It has now been applied to more than 50 viruses or virus strains and permits a precision and rapidity of work that was impossible with intact hosts or host tissues

Mumps virus is in many ways similar to the influenza viruses, Newcastle disease virus, and the para-influenza viruses Like these viruses it is absorbed by erythrocytes and agglutinates them, but its enzymatic activity, leading to release, is feeble. Cantell describes its biological properties, the difficulties met in attempts to purify it, and the variability of the response of hosts to it There are surprising, and still unexplained, differences in even such a simple host as the egg allantoic membrane so that, at some seasons, it is almost impossible to work with the virus This is experimentally inconvenient, but it is a salutary reminder that, in spite of the importance of information gained by physical methods, virus research remains a branch of biology

There are three purely biological articles, McNair Scott discusses poliomyelitis, Coxsackie, and other viruses that characteristically attack intestinal and respiratory tissue Bang and Luttrell discuss the nature of pathogenesis—that is, the relationship between host and parasite—in an extensive group of animal viruses No generalizations emerge from this except the not unexpected one that any treatment which affects the metabolism of the host will affect the behaviour of some virus in it Pereira has a similar theme he is concerned with changes in individual infected cells and the light they throw on the mechanism of virus multiplication and on the reasons why this is so often harmful to the host

This volume maintains the high standard of the series It could be argued that the absence of an article dealing specifically with plant viruses makes the book unbalanced, but this should not lead those primarily interested in plant viruses to disregard it for there is much here that, either by extension or analogy, will be of interest to them N W PIRIE

EVERYDAY USES OF ATOMIC ENERGY

The Release and Use of Atomic Energy

By Dr T E Allibone (Based on the Royal Institution Christmas Lectures) Pp xii + 158 + 20 plates (London Chapman and Hall, Ltd , 1961) 25*s* net

THIS book is based on the Christmas Lectures for young people which Dr Allibone gave in 1960 at the Royal Institution It follows the admirable tradition of those lectures in giving a clear and well-illustrated outline of the principal discoveries and concepts in atomic and nuclear physics, and of their application to electrical power generation. The first three chapters carry the reader from Neanderthal man to Calder Hall in a series of leaps from peak to peak in the curve of discovery over the period. Chapter 4 summarizes the leading features of the principal power-producing fission reactors in use or under development in Britain and the United States. In Chapter 5 some of the applications of radioisotopes are described. Finally, Chapter 6, one of the best in the book, is devoted to the work on controlled thermonuclear reactions, with a comment on the possibility that such reactions can be utilized to generate electrical power in the future.

In the course of the lectures Dr. Allibone tried to reproduce most of the crucial experiments in atomic physics over the past sixty years. These demonstrations must have fascinated his young audience. A hint of the fascination, and of the care with which the demonstrations were prepared, is given by the brief descriptions of the special experiments devised to illustrate principles, for example, the experiments to show the Doppler effect and the pinch effect in parallel conductors carrying a large current. The illustrations are clear and helpful and some are unusually vivid in the impression they give of classic experiments—the diagram of Mosely's apparatus is an example.

In one or two places one would have liked a little more detailed or exact description. The account of neutron slowing-down on p. 43, for example, leaves the reader uncertain as to why the neutron's speed is reduced. On p. 61 control of a reactor is described so briefly as to leave the impression that power output is varied simply by pulling control rods in or out and leaving them so. But these are minor defects in a book that should interest laymen of all ages and be of considerable use to teachers.

It is pleasant to see the cautionary tale of Frederick Worms (whose parents were not on speaking terms) preserved between hard covers.

THE WRITING OF AFRICAN GEOGRAPHY

The Republic of the Sudan

A Regional Geography. By K. M. Barbour. Pp. 292+42 plates. (London: University of London Press, Ltd., 1961.) 42s. net.

Africa

A Social Geography. By Anthony Sillery. Pp. xii+244+101 plates. (London: Gerald Duckworth and Co., Ltd., 1961.) 35s. net.

SOCIAL anthropologists often produce large volumes concerned with individual tribes, sometimes with single villages. Geographers perhaps have a different purpose, certainly a broader sweep; but if they study in sufficient detail and write at sufficient length they should manage to avoid those generalizations which the alert traveller or astute politician so often makes. Prof. Barbour, at one time a lecturer in what has become the University of Khartoum, and now head of the Department of Geography in University College, Ibadan, shows in his book on Sudan how this may be done. He has drawn extensively on his own field-work to bring out the significant regional variations in a country that, with an area of nearly a million square miles, is the largest independent State in the African continent.

This book is not a handbook of a vast territory, but it does provide a most useful introduction to it. A little less than half the book deals with Sudan as a whole, in terms of its physical and social geography and of its particular concern for the control and use of the Nile waters. There then follow chapters describing the six regions recognized by the author, who emphasizes for each its special characteristics and peculiar problems. Finally, there is an analysis of the factors contributing to the growth of a modern State in Sudan, and a conclusion that looks, with tantalizing brevity, at 'the way ahead', with the author's comment—applicable to so many countries besides Sudan to-day—that "the white man set in motion revolutionary changes in Africa, but responsibility for the future lies in the hands of the Africans themselves".

When more countries have volumes like this one on the Sudan and that on Nigeria in the same series by K. M. Buchanan and J. C. Pugh, or atlases such as those of Kenya or Tanganyika, both the white man and the African will be helped towards a deeper and more realistic understanding of the continent's present problems and future prospects.

Mr. Sillery, who was for many years a member of the Colonial Service and has latterly made some studies in African history, has tried to provide such understanding for the general reader who, in his own words, wants "some idea of Africa and of the people who live in it". It is a mine of up-to-date information about various parts of the continent, ranging from relief and climate to ethnology, agriculture, population, race relations and politics; it is written most readably and is very adequately illustrated by more than a hundred well-produced and usefully captioned photographs. Why the publishers and the author should call all this "social geography" is never made clear. Much, it is true, is basic material for the geographer (and many other students), but only rarely is it analysed geographically. It is significant, for example, that the book has only three maps, one of which shows relief by the "caterpillar method" associated with the map-making of more than a century ago. Furthermore, much of Mr. Sillery's information goes far beyond the limits suggested by the adjective "social". The titling of the book is indeed most unfortunate. Most geographers will almost certainly agree with my comment; other readers may understandably fight shy of a useful general work that has "geography" in its title. I may, of course, be wrong and the publishers right; they have had experience in this respect, since some years ago they produced a volume on the Far East with a similar title, also by an author who is not a geographer, and this book has recently gone into a third edition. It would be satisfying, however (certainly to geographers), if the world at large would accept that geography is no longer what it was once thought to be—capes and bays, products and tribes, and a general mass of miscellaneous and often unrelated information—and that real integrated geography of the kind generally taught to-day is most effectively written by trained geographers. Prof. Barbour's book is good evidence of what can be done if geographers are given the chance to travel, to observe and to analyse.

R. W. Steel

THE FUTURE NATURAL SCIENCES PROGRAMME OF UNESCO

By Dr HILLIARD RODERICK

Deputy-Director, Unesco Natural Sciences Department

THE United Nations Educational, Scientific and Cultural Organization (Unesco) was established in 1946 as one of the United Nations specialized agencies. (The specialized agencies of the United Nations are 15 intergovernmental bodies with wide international responsibility and specialized competence which have been brought into relationship with the United Nations by formal agreement.) As its name implies, it is devoted to education, culture and science, particularly fundamental science. Other members of the United Nations family also deeply engaged in science, usually of an applied nature, are Food and Agricultural Organization (FAO)—agricultural and fishery science, World Health Organization (WHO)—medical science, World Meteorological Organization (WMO)—weather science, International Telecommunication Union (ITU)—communication science, and International Atomic Energy Agency (IAEA)—peaceful development and application of atomic energy. Unesco is located in Paris and employs about 1,200 persons.

The Natural Sciences Department represents about 8 per cent of the professional staff and about 11 per cent of the regular budget of Unesco. In the 1963–64 regular budget of 39.0 million dollars, the substantive departments share as follows: Education (24 per cent), Culture (14 per cent), Natural Sciences (11 per cent), Mass Communication (11 per cent) and Social Sciences (8 per cent).

The Unesco charter states that one of the major objectives of Unesco is to increase and diffuse knowledge—in the case of the Natural Sciences Department, scientific knowledge.

What should Unesco, an intergovernmental agency devoted to science, do to increase and diffuse scientific knowledge? Primarily, it should serve as the agent of its 106 Member States in those international scientific matters which they cannot or do not wish to handle alone. Since most Member States have as yet no domestic policy towards science, it is unrealistic to expect them to have a foreign policy towards science and to know what they want done internationally. The result is that Unesco gets few specific requests and instructions concerning science from Governments. (However, it does receive many demands from the scientific community.) In a sense, Unesco was born before its time, but in another sense, it is already useful because it encourages Governments to co-operate in science and thereby to develop the healthy habit of participating in co-operative enterprises of mutual benefit.

Unesco's main method of action in science is arranging meetings to bring people of different nations together. Last year, the Natural Sciences Department held sixty meetings—seminars, conferences, working parties, panels of experts, etc. These meetings had widely varying purposes: to exchange scientific information, to survey a scientific field and plan what should be done in it by scientists and Governments, to found an international non-governmental scientific organization, or to create a regional or international research centre. But Unesco's job was almost the same in each case: it provided the initiative for the holding of the meeting and all the administrative services such as location, language interpretation, documentation as required, including agenda, working papers and commissioned reports; travel services for delegates to meetings, including visa arrangements, and in many cases payment for travel. Much of Unesco staff work requires a combination of creative imagination, scientific judgment, and diplomatic skill if international meetings are to present clearly scientific issues requiring action and possible alternatives for such action, and to arrive at a compromise which quickly leads to practical implementation.

Other types of activities which Unesco undertakes to increase and diffuse scientific knowledge are holding training courses, providing fellowships and equipment, supporting the preparation and publication of reports, sending survey missions and serving as the secretariat of a commission of Governments engaged in concerted oceanographic research.

To carry out these activities, the Unesco Natural Sciences Department has a professional staff of thirty-nine scientists, engineers and administrators from twenty nations, under the direction of Prof. V. Kovda, on leave from the University of Moscow, whose scientific speciality is soil geochemistry. Staff costs amount to about 30 per cent of the regular budget of the Department.

Outside its regular budget, and with much larger funds made available under the U.N. Technical Assistance and Special Fund Programmes, Unesco administers the provision of equipment, fellowships, salaries and travel of professors and scientists, to meet the needs of research and training institutions in developing countries.

Determination of Programme

Unesco tries to find out from the world scientific community what it believes should be done internationally. It does this by means of advisory committees and through four other means (Fig. 1). First, through the Unesco National Commissions: these are the channels which have been specifically created in each Member State for bringing the wishes of individuals and groups to the attention of Unesco.

Secondly, through the Government itself, in some nations, there exist ministries for science, councils for scientific policy, academies of sciences, etc. Some of these bodies have among their responsibilities the making of foreign policy in science. Where they exist, they are a useful means of making the scientist's opinions known in Unesco.

Unesco General Conference meets, modifies and approves 63 64 programme and budget
Starts executing 63 64 programme and receives suggestions for 65-66 programme

Fig. 1. Initiation and determination of Unesco natural sciences programme

The third way is up the pyramid of scientific non-governmental organizations. Here a suggestion brought to the attention of the national scientific society is forwarded to the appropriate international union, and then, through the mechanism of the International Council of Scientific Unions (ICSU), the Union of International Engineering Organizations (UATI) and the Council for International Organizations of Medical Sciences (CIOMS), it is presented to Unesco.

Finally, there is the direct approach to Unesco by letters and personal contacts with the Unesco secretariat. Using the information received through these four channels, Unesco prepares a draft programme about eighteen months before it is to become operational. The cycle of programme initiation, modification, and legislative approval is shown in Fig. 1. In this cycle, the 1963–64 proposed programme, presented here, has already passed the Executive Board (a supervising committee made up of representatives of twenty-four nations) and is being modified slightly for presentation to the Unesco General Conference in November 1962. (The General Conference is a legislative assembly at which representatives of 106 Member States make known the wishes of their Governments and approve the programme and budget. It meets once every two years to determine the programme for the following two years. Often, new projects originate at the Conference.) Although it is almost too late to suggest major alterations, it is hoped that scientists and scientific organizations will offer criticisms and suggestions to permit a better detailed formulation of the 1963–64 programme. Suggestions for important changes should reach Unesco by mid-1963 to be considered in preparing the 1965–66 draft programme.

A ten-year science programme. In 1960, Unesco developed a ten-year plan in science (approved by the Unesco General Conference in November 1960) which has as its objectives (*A*) to promote the advancement of science through international co-operation, (*B*) to encourage the development of certain fundamental scientific activities which can be foreseen as being directly related to the future welfare and economic progress of mankind, (*C*) to assist Member States in improving their level of science and widening its applications to their economic growth.

The 1963–64 Programme

With the above objectives in mind, the proposed 1963–64 programme has been constructed along three main lines: (*A*) promotion of international co-operation in science, (*B*) co-ordination of research in earth sciences and natural resources, (*C*) aid for national scientific development.

It is made up of 21 individual programmes, projects and continuing activities gathered into nine broad fields (Fig. 2 and Table 1). The annual regular budget for 1963–64 is set at 2·15 million dollars, which is an effective increase of about 6 per cent over the period 1961–62. In 1963–64 the extra-budgetary funds to aid the developing nations are 2·5 times the regular budget and will be distributed as shown in Fig. 3.

(*A*) Promotion of International Co-operation in Science

Under this very general heading are activities (i) to support the most important international structures for the exchange of scientific information—the international non-governmental scientific organizations, (ii) to improve scientific documentation by integrated co-operative planning, (iii) to strengthen international co-operation for the advancement of research in the life sciences and chemistry.

(i) *Support for international non-governmental scientific organizations.* Since the arranging of international meetings to exchange scientific information has been done traditionally and most efficiently by the non-governmental scientific organizations,

Table 1. Summary of Unesco Natural Sciences Programme 1963–64 Regular Budget

Field	Project	Year started	Funds for 1963–64 (*b*)	Stage (*c*)	Present objectives (*g*): Co-ordination of research	Present objectives (*g*): Concerted research programmes(*e*)	Present objectives (*g*): Training of scientist
(*A*) International Co-operation in Science							
1. Subventions to non. gov. sci. organiz.	1 (*a*)	1947	541	cont.			
2. Co-ordination of sci. documentation	2 (*a*)	1949	170	plan.	×	×	
3. Advancement of laboratory research	3 Brain research	1959	70	act.	×		×
	4 Cell biology	1955	90	plan.	×		×
	5 Chemistry	1963	30	stim.			
(*B*) Co-ordination of Research in Earth Sciences and Natural Resources							
4. Scientific studies relating to natural resources	6 Scientific surveys	1961	45	stim.			
	7 Making of scientific maps	1959	100	cont.	×		
	8 Scientific hydrology	1963	50	study	×	×	
	9 Soil biology	1961	30	study	×		
	10 Arid zones studies	1951	290	act.	×	×	
	11 Humid zones studies	1954	120	plan.	×		
	12 African conferences	1961	85	stim.			
5. Geophysics and space sciences	13 Seismology	1961	45	study	×	×	
	14 Geophysical data	1957	30	study	×		
	15 Space sciences	1961	60	stim.			×
6. Marine sciences	16 Intergov'tal Oceanogr. Comm.	1961	70	cont.	×	×	
	17 Int. Indian Ocean Expedition	1961	50	act.	×	×	
	18 Marine sci. regional progr.	1954	343	act.	×		×
(*C*) Aid to National Scientific Development							
7. National science policy	19 (*a*)	1961	80	cont.			
8. Aid to technological research	20 Standards and testing labs.	1963	30	stim.			
9. University education in sci. and technol.	21 (*a*)	1961	204	cont.			×

(*a*) Field and project have same title; (*b*) In thousands of dollars; (*c*) Cont. = continuous activity; stim. = stimulation; plan. = planning act. = action; (*d*) Co-ordination of research is obtained by means of committees, working parties, surveys, special review studies, etc.; (*e*) By concerted research is meant research co-ordinated by agreements *before* or *while* being undertaken, rather than after as is usual in (*d*); (*f*) By fellowships, training courses, etc.; (*g*) All projects aim at increased exchange of information.

Governments have continued to support Unesco subventions to these organizations. Unesco provides financial support in the form of subventions to three of the largest international non-governmental scientific organizations—ICSU, UATI and CIOMS—which, annually, hold more than 100 scientific meetings and bring together more than 10,000 scientists. The funds provided by Unesco pay for about one-half the organization's costs in holding these meetings. Unesco will increase its total funds for these subventions in 1963–64.

(ii) *Co-ordination of scientific documentation at the international level.* For a number of years, Unesco has studied various facets of the problem of enabling the individual scientist to find out rapidly and easily if others have already done what he is trying to do and if their results are relevant to his own work. Unesco's role will now be to promote an integrated approach to scientific documentation bringing together the international scientific and professional organizations such as the International Federation for Documentation (FID), the ICSU Abstracting Board (ICSU–AB), the International Federation of Library Associations (IFLA), the International Organization for Standardization (ISO) and government bureaux concerned with the different aspects of scientific information at the national level. Unesco will set up an Office of Scientific Information, somewhat similar to its Office of Oceanography, to carry out Unesco's programme in documentation and to serve, if required, as secretariat in carrying out a ten-year plan for the co-ordination, on a world basis, of scientific documentation.

In 1963, five working parties will consider the problems in: primary scientific publications, abstracting activities, translation and terminology, mechanization and coding, information on and proceedings of congresses and scientific meetings.

After the working parties have met, there will be a summary planning meeting in 1964 of governmental and organizational representatives and experts in the aforementioned fields. The summary planning meeting will determine, on the basis of reports from the earlier working parties, what steps must be taken to improve the availability and usefulness of scientific information and what the responsibilities of the various existing organizations should be. On the basis of this, a ten-year plan for action, including the appropriate mechanisms, will be drawn up and agreed to by the responsible parties.

(iii) *Co-operation for the advancement of research in the life sciences and chemistry.* Because knowledge of the biology of the cell and the function of the brain has been increasing at a remarkable rate in recent years and may be opening an era as fruitful in biology as the discovery of the structure of the atom was in physics, Unesco has singled out these two related fields for support. In brain research, further progress is more than ever dependent on the collaboration of scientists from the different disciplines (as far apart as communications engineering and neuro-surgery) working together on common problems, and on an increase in the number of well-trained scientists. Unesco has therefore developed with the International Brain Research Organization a joint programme to organize interdisciplinary research teams to sponsor fellowships and to conduct a survey of existing institutions for research and training. A long-term co-ordinated research project on the multi-disciplinary aspects of brain growth and development will also be started.

Within the past five years there have been rapid advances in cell biology, particularly towards clarifying mechanisms of genetic control at the molecular level; however, progress on a world-wide basis is being limited by the lack of sufficient communication

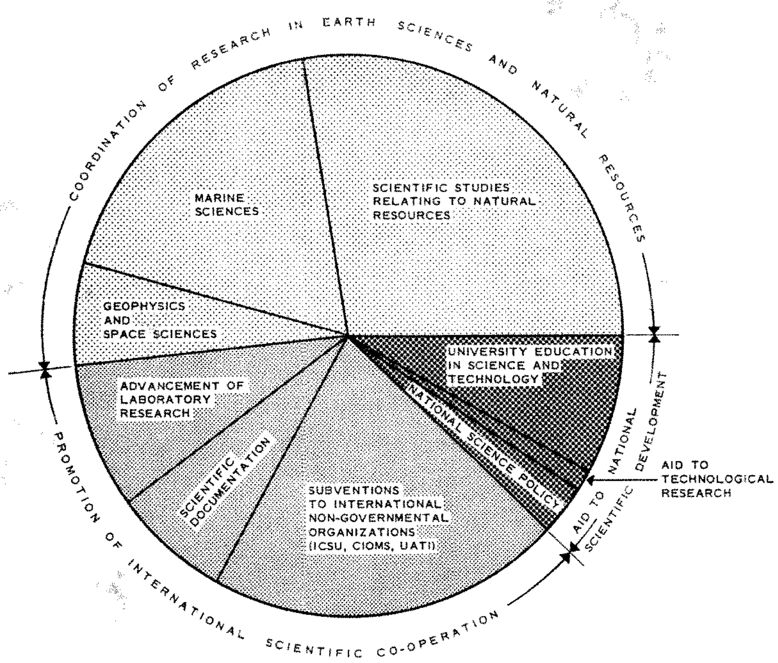

Fig. 2. Proposed programme in natural sciences for 1963–64. Distribution of regular budget 4·3 million dollars for two-year period

of new ideas and techniques in experimentation, and lack of co-ordination between research programmes being developed at the more active cell biology research laboratories. To enable research centres, as well as individual cell biologists, to improve their communication and to co-operate in the planning of research programmes, Unesco will undertake both a pilot project to associate a small group of research laboratories, and a project to help the cell biologists organize an international cell biology organization (ICRO). It is expected that the directors of the associated research laboratories will meet to co-ordinate their research planning and Unesco will help them through fellowships to provide for the exchange of research scientists. The proposed ICRO will concern itself with voluntary concerted research planning between a large number of associated cell biology research centres, and with the problem of raising the scientific level of cell biology research throughout the world.

In chemistry, Unesco will aid the International Union of Pure and Applied Chemistry in holding a series of specialized small meetings to increase the exchange of information on the theoretical aspects of catalysis.

(B) Co-ordination of Research in Earth Sciences and Natural Resources

The promotion and co-ordination of earth science research make up the largest portion of the regular programme of Unesco Natural Sciences Department and are undertaken because the need for international co-operation in these in studies is both obvious and great; these fundamental studies are required before the exploitation of natural resources for human welfare and can be effectively undertaken. Major activities to be continued include: (i) standardization of earth science surveys and map making; (ii) improvement in the handling and diffusion of geophysical and seismic data; (iii) marine sciences; (iv) arid zone studies; (v) humid tropic zone studies.

(i) *Standardization of earth science surveys and map making.* Unesco will hold in 1964 an international inter-disciplinary conference on survey techniques, particularly photo-interpretation and other aerial methods, used for natural resources exploration in soils, botany, geology and hydrology. The purpose of this conference is to bring together both makers of surveys and those who use their results such as geologists, botanists, hydraulic engineers, land-use planners, etc., in order that future surveys may be arranged to produce the maximum amount of integrated scientific information possible for the users.

Furthermore, the scientific bodies which are preparing international small-scale geological, metallogenic, tectonic, soil, hydrogeological and vegetation maps with universally accepted legends and nomenclatures will receive administrative services and financial aid from Unesco.

(ii) *Improvement of geophysical and seismic data handling.* Eleven international non-governmental services which receive geographical data on a routine basis from a total of 1,600 observing stations, and then reduce, analyse and distribute them to interested astronomers, astrophysicists, geophysicists, oceanographers and other scientists, from the Federation of Astronomical and Geophysical Services (FAGS) (these services are the following: International Time Bureau, International Latitude Service,

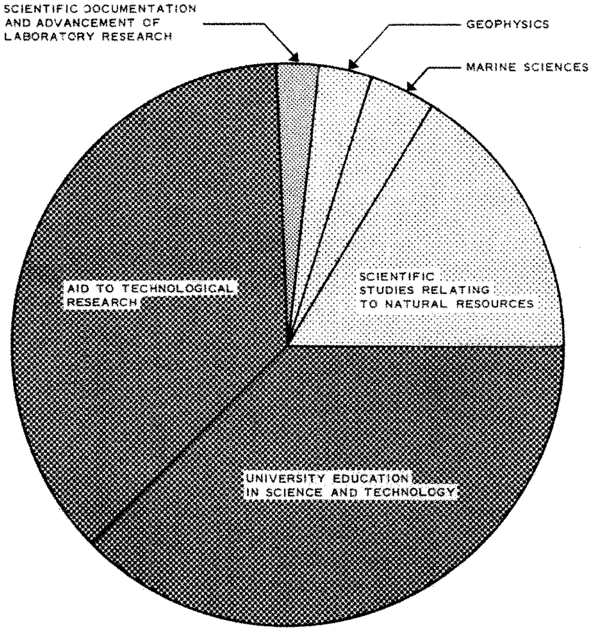

Fig. 3. Aid for national scientific and technical development. Distribution of extra-budgetary funds for developing nations 10·8 million dollars for two-year period 1963–64.

International Gravimetric Bureau, International Seismological Bureau, *Quarterly Bulletin of Solar Activity*, Ursigram Bureau, International Seismological Summary, Permanent Service of Geomagnetic Indices, Permanent Service of Mean Sea Level, International World Days Service, International Centre for Earth Tides) and receive financial support from both ICSU and Unesco

As a start towards providing FAGS with the facilities that it wished and needs to meet the modern demand for new data in a form convenient for immediate use, Unesco proposes to bring together interested Governments and organizations in working parties to agree on how to improve the handling of seismic data Presumably a form of international centre for the treatment of seismological data having appropriate electronic computing facilities will be required

Unesco will also hold an international conference in 1963 on seismology and its applications to earthquake protection This conference will review the results and recommendations of the Unesco–IUGG survey missions undertaken since 1961 to the various seismic belts of the Far East, Andes Mountains of Latin America, the Mediterranean, the Caribbean and East African regions by professional teams of observational seismologists, seismo-geologists and earthquake engineers This conference, with the goal of a more complete understanding of seisms and their origin, is expected to determine what can be done to improve the operation of the existing seismic stations, where new stations should be set up, and how to integrate the flow of data dispatched from the various stations in the most efficient way

In addition, it is expected that the conference will suggest action that should be taken at the governmental level to improve the protection of populations against effects of earthquakes

(iii) *Marine sciences* Unesco will expand its activities in support of marine sciences These have two major aspects, namely (1) co-ordination of concerted national efforts in marine sciences through the Intergovernmental Oceanographic Commission (IOC), (2) aid to oceanographic research and training in selected regions of the world In addition, there is a world-wide competitive fellowship programme for both shipboard work and study abroad, as well as support for the exchange of information through a *Unesco Marine Sciences Newsletter*

The Unesco Office of Oceanography serves as the secretariat of the Inter-Governmental Oceanographic Commission and functions as a liaison body in carrying out the agreements and recommendations of the Commission The role of the Secretariat of the IOC in the co-ordination of the International Indian Ocean Expedition (IIOE) will increase significantly in 1963 This expedition has been organized by the Scientific Committee for Oceanic Research (SCOR) of ICSU, with the aid of Unesco

During 1963–64, peak activity will be reached with the operation of between 10 and 15 survey ships in the Indian Ocean Although the Expedition has been envisaged as a loose combination of individual scientific expeditions, in order that the maximum flexibility be realized, it is necessary that certain activities be agreed on in advance Working parties from the various ship-operating organizations are thus brought together by SCOR and Unesco to co-ordinate tracks and to standardize methods and equipment In physical oceanography, for example, it is desirable to agree on methods of measuring oceanic currents and the salinity of sea-water if comparability of results is to be attained. In chemistry, methods for determining dissolved gases and trace elements involved in biological cycles are necessary In marine biology, methods of collecting plankton and determining biological productivity must be agreed on and adopted In addition to arranging the above working parties with funds provided by Unesco, the Secretariat will later convene similar groups to appraise the results obtained and to prepare joint reports for publication of atlases of the region

Unesco will aid the IIOE by providing funds and expert advice for the creation of the Indian Ocean Biological Centre at Cochin, India It is expected that each ship will send a portion of its plankton obtained with standard nets to Cochin, where the samples will be sorted into major groups The curator of the international collection will send samples on a world-wide basis to those experts most interested in them Finally, the classified holotypes will be deposited in the international reference collection and will serve the entire Indian Ocean Region

To stimulate national efforts in oceanographic research and training, Unesco will help develop a number of marine science activities on a regional basis The Indian Ocean, South-East Asia, North Latin America, and West Africa regions are four regions of the world where projects are already in existence or planned, but where limited staff and facilities are restricting their execution Unesco's activities will reinforce these projects in a way to increase the long-term growth of local marine sciences

In each region, it is hoped eventually to establish a regional training centre equipped with a suitable research vessel, laboratory facilities, class-rooms and instructional staff During the next few years, Unesco will encourage the development in each country of at least one centre of size and variety sufficient to ensure the rapid growth of national activities in marine sciences Finally, for each region, Unesco will help local institutes to co-ordinate their research and training activities and possibly to develop an overall regional research programme For example, in the Indian Ocean region, Unesco's activities will be organized to fit the activities of the IIOE Support will be given to both India and Pakistan for their participation in the Indian Ocean Expedition by providing equipment to one oceanographic ship from each country

(iv) *Arid zone studies* The arid zone research programme of Unesco has among its objectives, an increased systematic study of the scientific problems arising in the arid and semi-arid zones of the Earth Of particular importance to these climatic regions are salinity, ground-water hydrology, plant–soil–water relationships and, of course, climatology Unesco's programme of the past ten years has been to stimulate greater interest in these and related problems by scientists of the arid zone regions and by those in other parts of the world The programme consists of four parts (1) exchange of information through meetings and publications, (2) training courses and fellowships, (3) co-operative planning of surveys and research through special advisory committees, (4) support of special studies, reports and maps

During 1963–64, the project will be extended to the arid zones of Latin America A large international conference will be held to review present-day scientific knowledge of the arid regions of the various Latin American States and to stimulate such studies, in relation to these nations, as surface hydrology, geology and ground water, meteorology, soil sciences, plant and animal ecology and physiology. Finally, interdisciplinary problems such as geo-morphology and the integrated approach to arid zone research, efficient uses of water, and optimum grazing land use, will be discussed.

Also, the nations of North Africa will be encouraged to make a co-operative survey of their artesian water basin and to prepare international maps of it.

(v) *Humid tropics studies.* Similarly, the humid tropics programme has, among its objectives, an increased systematic study of scientific problems of the humid tropic regions of the Earth. Of particular importance of these climatic regions are laterization of the soils, conditions controlling extension of the savanna into the tropical forests, and equilibrium conditions between land, sea and fresh water in the delta areas. One should mention also the biology, functions and control of termites in the tropics and the collection, preservation and taxonomy of tropical flora and fauna.

During 1963–64, three symposia will be held on humid tropics problems dealing with laterization, delta areas, and relationships between the savanna and the tropical forests.

Also included under the programme to co-ordinate and promote earth sciences research are two small continuing projects to provide modest support for exchange of information in space research and soil biology through the appropriate professional societies, and a new project to initiate a long-range programme of international co-operation in scientific hydrology. This project will have as its objective a world-wide study of water cycles and will provide a scientific basis for an evaluation and use of world water resources.

(C) Aid for National Scientific Development

Although much of the regular programme of Unesco in science provides assistance to Member States, there is a group of activities where direct aid to Member States for their scientific development is the prime motive. These continuing activities are: (i) comparative studies relating to national science policy, (ii) a project to provide information and material for the improvement of university science education, and (iii) a small project to aid nations in the establishment of testing and standards laboratories.

(i) *National science policy.* Unesco will continue its comparative studies relating to the national science policy of Member States, with particular emphasis on the administrative structure required for the organization of research at the national level, on scientific manpower and financing problems and on national scientific research policy. Unesco also sends specialists to the developing nations, on Government request, to help them set up their own national research academies and science councils or fundations.

(ii) *Improvement of university science education.* Comparative studies of curriculæ, laboratory practice and teaching methods at university-level will be undertaken with the aid of the international scientific unions in physics and chemistry and will eventually be started in biology and geology. Information provided should aid universities in the process of remodelling their educational structure to provide better and more modern scientific education.

Unesco source books will be prepared in physics, chemistry, mathematics, biology and geology as teaching aids and as handbooks of modern practical information not readily available in a single volume, for students and teachers in the first and second years at the university. The manuscripts will allow for cheap production in local languages.

Furthermore, Unesco will support international postgraduate training courses and schools established in the developed nations in selected disciplines such as experimental physics, mathematics, chemistry, cell biology, plant biology and soil sciences. This programme will help developing countries to acquire a nucleus of highly trained scientists, for both teaching and research work.

Field Science Co-operation Offices

To implement its programme and serve local scientists, Unesco operates four Field Science Co-operation Offices at Djakarta, New Delhi, Cairo and Montevideo. The work of each Office includes: aiding the formation of regional scientific centres, such as the Latin American physics and mathematics centres, holding annually four or five scientific seminars and training courses of specific regional interest as, for example, the symposium on the vegetation and soil of limestone formations in South-East Asia planned to be held in Malaya in 1964, and acting as a clearing house for scientific information and material. In 1963–64, the Offices will emphasize the improvement of university science teaching.

Although Unesco does not yet have a science office in tropical Africa, it is developing a programme of local interest to that area. A large conference will be organized there in 1963 on research and training relating to African natural resources.

Extra-budgetary Aid for National Scientific Development

Unesco, using funds of the U.N. Technical Assistance Programme, will provide for about a hundred professors and scientists to go to forty developing countries. These experts will teach at the university, improve curricula and laboratory practice and, in some cases, advise ministries on scientific matters. Also under this programme, about a hundred fellowships will be provided, enabling young scientists from developing countries to train abroad. Using the funds available from the Special Fund of the United Nations, Unesco will continue to build up six institutions for research and technological education and will start six new projects. (It is expected that 7.4 million dollars will be provided by the Special Fund for the operation of these twelve projects during 1963–64.)

Discussion

Twenty-one projects, programmes and continuing activities (Table 1) of greatly varying size and objectives have been chosen for Unesco's attention from the broad spectrum of modern science. Concerning them, three questions immediately come to mind: (I) Why this number of projects? (II) Why this distribution of funds among the projects? (III) Why these projects and not others?

(I) *Number of projects* It is evident that Unesco must develop its programme as a compromise between almost unlimited requests for projects from scientific and Governmental groups in 105 nations and the limited resources at its disposal The proposed programme, made up of twenty-one carefully chosen projects, aims at a satisfactory compromise with the following characteristics

(i) Those activities have been chosen which appear most suited for international action Thus, projects in support of international co-operation for the exchange of scientific information utilize approximately a half of the total resources of the natural sciences regular programme, another quarter will be spent to meet the needs of research co-ordination at the international and regional levels, while the remainder of the budget is to support the training of scientists and to stimulate research at the national level

(ii) The programme has been planned to ensure its concentration in three broad fields (actually, as noted in Table I, five large projects account for two-thirds of the regular budget)

(iii) The programme has been planned to be of interest to all nations in an equitable manner Thus, 56 per cent of the regular programme is of general scientific interest, another 10 per cent is of particular interest to the developing nations, while the remaining 10 per cent is aimed at the advanced nations

(II) *Distribution of funds* It has been argued that with such limited funds and with so many requests for programmes, Unesco has dispersed its efforts by starting a large number of projects relatively weakly supported financially To answer this argument, it is necessary to observe that projects usually evolve through four stages study, stimulation, planning and action, and in each stage require different amounts of expenditures

To illustrate this concept, the marine sciences project may be presented as an example In 1954, when this project was launched by the General Conference, only a general objective had been set and neither specific goals nor the means of attaining them were clearly defined

In the course of the following seven years, the project evolved through four stages

(1954–55) A study-stage during which working parties met and decided on preliminary requirements

(1955–59) A stimulation-stage during which marine science was stimulated by an increased flow of information supplied by seven Unesco-supported conferences

(1955–59) A planning-stage during which the International Advisory Committee in Marine Sciences was created in 1955 After a series of meetings, the Committee advised the Organization in 1958 to carry out a concrete programme of concerted international action in marine sciences

(1959–) An action-stage during which Unesco took measures to establish an Inter-governmental Oceanographic Commission which met for the first time in 1961 and initiated plans for joint scientific expeditions operated by interested Member States to eleven separate regions of the world ocean

The foregoing example demonstrates how a general idea may develop in seven years into specific international action on a world-wide scale, with a ten-fold increase of financial resources, if circumstances are ripe for such evolution

The time-scale for this chain of project evolution is long because of the varying world outlook of nations, the slowness with which scientists and Governments become informed and arrive at opinions about a project, the multiple consultations required for decision making, and because of modest funds which limit the rate of activity Thus it requires at least two years to get even a small project started as part of the programme, it usually takes another four to six years to reach the action phase, and perhaps four to six more years to complete the action, depending on its character

In this process, one of the limiting factors which could be changed is money Unesco's annual regular budget in science is of the order of magnitude of 0 1 per cent of the sum total of funds spent on basic research by all the nations International money is scarce, but it can be very useful, it can usually pay for things which national money cannot, such as the expenses of international meetings or publications If wisely spent for stimulation or for a concerted programme, it should cause much more national money to be spent in the selected field and in a more effective manner

(III) *Selection of projects* The priority given to projects has been determined by the following considerations (1) Unesco's ten-year plan in the field of natural sciences, (2) the stage of evolution and age of continuing projects, (3) the maturity of new projects with respect to international action, and (4) the desire and the ability of Member States to provide appropriate investment of their own funds and scientific resources in joint activities co-ordinated through a Unesco project the funding of which is necessarily limited

The question of whether the proposed selection of projects in 1963–64 makes the best use of the available funds for the international promotion of science must also be considered in the light of the following basic questions

(1) Should Unesco support—and for how long—projects which stimulate a field of science but the results of which cannot be easily measured ?

(2) In the light of other immediate needs in international science are concerted action projects such as marine science or scientific hydrology proper types of activity for Unesco considering their long gestation period ?

(3) What should be the ratio of new to continuing projects, considering the great length of time required for projects to mature ?

(4) Are staff studies and clearing house activities such as the programmes on information about the national science policy and university science education more suitable for Unesco than projects to co-ordinate or promote research, considering their low costs and predictable rate of activity ?

Since the 1963–64 programme has evolved under the guidance of scientific committees of national Commissions and with the advice of international advisory committees, these questions have obviously been considered The resulting programme thus represents a practical compromise of different points of view Nevertheless, the need for reconsideration of these questions is a recurring one, their formulation is intended to aid deliberation about the future programme of Unesco

One of the reasons for reviewing Unesco's role in science and its proposed programme for 1963–64 is to solicit suggestions and criticisms, only through them can future programmes of Unesco truly represent the needs of scientists and be really effective in making for international co-operation in science

One may ask about the value of Unesco's programme to the individual scientist, to the development of science, and to mankind As an individual, one is most likely to get direct benefit from Unesco only if he happens to hold a Unesco fellowship or attend one of the 150 international meetings annually supported by Unesco

Although the development of science proceeds through individual efforts supported by local expenditures which are larger than Unesco can provide even to the poorest of nations, Unesco's aid has often greatly stimulated local scientific growth Furthermore, in the earth sciences Unesco's role of co-ordinator of national efforts has proved essential, and the benefits to science have been indeed large

Finally, there is the ultimate value to mankind of Unesco's efforts, the fact that scientists and Governments of many nations can work together through an intergovernmental agency for the common advancement of human knowledge should be both an inspiration and an example to statesmen and laymen faced with the diversity and dangers of competitive ideologies and nationalisms

INDUSTRIAL CHEMISTRY SURROUNDING GOLD*

By The Right Hon Lord FLECK, K B E , F R S

I HAVE been asked to discuss some definite theme in the history of science and technology in the nineteenth and twentieth centuries, particularly a theme which might illustrate the action and interaction between developing technology and economic conditions and where industrial needs and purely scientific developments have suggested (or failed to suggest) problems for each other It is perhaps difficult to fill this specification fully, but if the sequence

enlarged demand
leading to
better process
leading to
industrial production of new materials

is of interest by its reactions and interactions, then I think the study of gold is worthy of some consideration In the latter decades of the nineteenth century the ever-present demand for gold increased There was then the invention of the cyanide process—a much better process in every way than had been available before then That had to be accompanied by better processes for cyanide manufacture, thus leading to what in itself is a sizeable chemical industry So therefore I propose to review gold production and some of the aspects of industrial chemistry associated with it I am happy to do what I can with this subject for two reasons first it is a subject in which I have been much interested over many years, although I must disclaim any suggestion that I can approach the subject as an economist My interest is decidedly amateurish Secondly, it so happens that I was brought into personal contact with some of the personalities, particularly two, John Stewart McArthur and George Thomas Beilby, who played some decisive part in the industrial part of the story, and I would like, before it is too late, to put on record some personal information That personal information is, I am afraid, largely undocumented, but nevertheless it may be helpful in understanding the course of industrial events

The subject of gold has excited the interest of mankind through countless years There is reason for believing that native gold and native copper were the earliest of mankind's attempts at working metals Gold was widespread, and in the ancient world it was distributed through, and worked in, for example, Arabia, India, Persia, Caucasia, Asia Minor and the Balkans It was in Egypt that there appears to have been the most regular production and *The History of Technology* gives 30 kgm per annum as the regular output from the Nubian mines I shall be using tonnes as my units for gold production, so that this figure of 0 03 tonnes per annum is not at all large compared with the figures that I will presently put before you Rameses II in the thirteenth century B C was concerned about the number of gold washers who died in the Nubian desert

There is very little that can be usefully said about the quantities of gold produced up to the time of the discovery of America The situation in the years after that date, however, is very different, and we are indebted to the researches of Adolph Soetbeer of the University of Gottingen for bringing up much quantitative information, writing in the 1890's His information is shown in Fig 1 extended up to 1961

Gold production is usually given in so many thousands or millions of fine ounces, but I have transferred my units into tonnes to make it easier to make mental comparisons with quantities of production in the chemical industry

After the discovery of America, owing to the strength of the Spanish situation, most of the gold

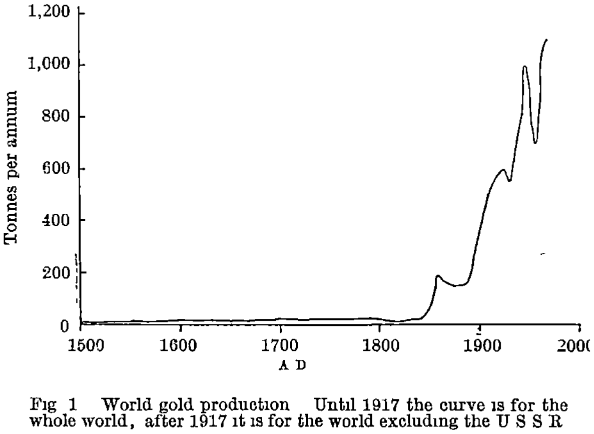

Fig 1 World gold production Until 1917 the curve is for the whole world, after 1917 it is for the world excluding the U S S R

transferred from America to Europe was channelled through Madrid for many years, and thus it can be understood why we can place a measure of some accuracy on the early figures of gold production. Certainly, so far as I am aware, Soetbeer's figures have not been challenged.

---

* Substance of a lecture delivered in the series "Science and Economics in Chemical Technology" at All Souls College, Oxford, on May 2

Our figures start at the beginning of the sixteenth century when the annual world production was an amount in tonnes that could be counted on the fingers of the two hands—something of the order of 5–8 tonnes per annum. By the beginning of the eighteenth century these figures had increased to double figures, largely from Brazil and then in the middle of the nineteenth century, owing to the Californian and Australian discoveries, it rapidly increased into hundreds of tonnes per annum.

"For many years after the discovery of America, the output of new gold there was small, and much of the gold which was exported to Europe in the sixteenth century seems to have been obtained by looting from the natives the gradual accumulation of centuries. The first important source of new gold was discovered in New Granada (Colombia) in 1537, and throughout the seventeenth century that country remained the world's largest producer with about 40 per cent of a world annual output of under 9¼ T. Towards the end of the seventeenth century the discovery of the deposits of Brazil brought a new sharp rise in world production, and in the eighteenth century Brazil alone is estimated to have produced 45 per cent and South America as a whole 80 per cent of the world output of about 18½ T. a year.

"During the first 40 years of the nineteenth century South American production gradually declined, and world output fell off despite some increase in Russian production. But the discovery of gold in California in 1847, followed by the discoveries in Australia in 1851, brought a rapid increase in world output from 15½ T. to 180/190 T. a year. In the 1860's the alluvial deposits began to show signs of exhaustion, and the gradual increase in lode mining was not sufficient to prevent a fall in world output from 200 T. a year in the late 1850's to under 155 T. in 1886.

"This proved to be the lowest point reached. South Africa had already been producing small quantities of gold from alluvial deposits and lode mines, but the discovery of the Barberton gold field in 1882, and of the infinitely more important Witwatersrand field in 1884, opened the way for a new great expansion in world output. . . ."

We see from Fig. 1 that after the 1890's there was a surge forward interrupted as was natural by the Boer War troubles until the depression after the First World War. The upward trend was resumed and reinforced by the Second World War to a maximum about 1941. This was followed by a drop which was then counteracted by the incoming of the Free State gold and to-day we are again having record productions, essentially of course dominated by South African production.

We are now in the position that the output of gold for 1961 is at a record level, essentially due to the output from South Africa at 1,100 T. per annum. This record is not great over 1942 period, but it is definite although the margin is small.

The figures I have quoted are to the best of our knowledge the global world figures until 1917, the date of the Russian Revolution, since when the figures exclude U.S.S.R. production. The U.S. Bureau of Mines has published estimates for the U.S.S.R. and their latest figures are estimates for present-day production at between 280 T. and 315 T. per annum. This will give us a probable global production of gold for the world, including the U.S.S.R., of the order of 1,400 T. per annum. I have only two additional comments of a general nature to make. First, it is worthy of acknowledgment that South Africa has made a remarkable achievement in raising its gold output from 410 T. in 1954 to 625 T. in 1959—a 50 per cent increase when various rumblings have been heard that the price of gold should be raised. The other production figure which should be noted is the increased production from Ghana, 21 T. in 1954 to 28.5 T. in 1959, a 35 per cent increase, which brings Ghana nearly to the same level as Australia. There is no reason, so far as I know, to suggest that there are vast quantities of gold in Ghana awaiting exploitation, nevertheless, if the gold resources there can be increased over the present, or even maintained at the present relatively high level, there may be much significance to the economic prosperity of Ghana in the gold situation there.

That is the story of gold production in a simple form up to the present day.

Looked at in the cold light of industrial production of a thousand and one commodities in the context of world tonnages, 1,400 seems a very small figure indeed for a commodity which is so much in the eye of peoples all over the world. But no one can deny that, small as it is, the gold production has many actions and reactions in all sorts of quarters.

The first one that I would mention was an economic one. In many books there is reference to the economic consequences of the influx of gold in the sixteenth and early part of the seventeenth centuries to Spain, and then the outward spread of gold from there to cover all Europe. It had a great effect in pushing up prices for many commodities. The situation was very fully examined, for example, by Jacob, writing in 1832 in London. I can also quote Moncada, writing in Madrid in 1619: "Before the discovery of the Indies he who possessed 100 reals was as rich as he who now enjoys 500 for with the abundance of gold and silver its value has fallen".

No doubt the earliest gold production was native gold which could be comparatively easily rolled and worked into gold vessels and other objects. To collect the small particles of gold would, however, be a slow and tiresome business, and so it is easily understood that alternative techniques would be looked for, thus we have the introduction of amalgamation somewhere around about the early years of the Christian era; certainly it was well established by the Middle Ages, and amalgamation has continued down to recent times. Amalgamation, however, that is, the process of picking up small gold particles by mercury, filtering the liquid amalgam away from extraneous material and then distilling off the mercury to leave as a residue relatively pure gold, was never a very satisfying process to either a trained engineer or to a trained chemist. To begin with, the process could not be applied to ores relatively poor in gold. It was applicable to ores containing at least 4 oz. of gold per ton only.

When it is remembered that many of the South African ores which to-day are being worked economically contain only some 5 dwt. it can be seen that the industrial application of amalgamation processes has a limited field of application. Then again, the operation of amalgamation processes is very inefficient—40 per cent recovery is often spoken of, seldom did it reach 60 per cent. That, however, was the main process of gold recovery until nearly the end of the nineteenth century. Then there was increasing demand for gold as that century moved towards its end, no doubt stimulated by the economic forces at work throughout the world. The gold standard was a very real thing with us, and trade and commerce, both nationally and internationally, were developing and important factors and required increased quantities of gold for their operations.

So we arrive at the 1880's, when important things began to happen in the gold industry. As I have already stated, in 1882 gold at Barberton in the Transvaal was discovered, and then in 1884 came about the discovery of gold on the Rand. These, of course, were not alluvial deposits, and in the case of the Rand, particularly, the gold was disseminated through the rock in a very fine state. There was therefore very considerable pressure on the mining engineers and mining metallurgists to have a better way of isolating the gold than the crude amalgamation process in operation up to that time.

And now I would say a few words about chemical industry in Great Britain at that time. In 1881 the Society of Chemical Industry was formed in Britain, so, apart from the dyestuffs industry, there was a vigorous heavy chemical industry based essentially on salt and sulphur.

Signs of this vigour in Europe as well as in Great Britain were the arrival from America of H. Y. Castner in 1886 with a process for the chemical production of aluminium, and the patenting in 1886 in France of a process for the electrolytic manufacture of aluminium. In 1888 there was patented an electrothermal process for phosphorus manufacture.

Chemical processes using electricity were very much in fashion, and so it is not surprising that another American, Henry Renner Cassel, had landed in Britain and proclaimed that he had an electrolytic process for the isolation of gold. That again was in 1884. It was in a climate of broad chemical industrial activity that he interested that very astute and courageous Glasgow chemical manufacturer, Sir Charles Tennant, in his venture. The process turned out to be a bogus one, and Cassel took advantage of a wave of unjustifiable optimism in his process to sell out his founders shares and go back to America with his ill-gotten gains. But quite a lot was saved out of the wreck of the Cassel Gold Extracting Co. John Stewart McArthur was a chemist employed by the Tharsis Copper Co., of which Sir Charles Tennant was chairman, and in his private time McArthur was interested in gold. Many years later, during 1910–20, I got to know McArthur very well, in connexion with work quite unconnected with gold, and have heard from him some of the details of the development of the McArthur–Forrest cyanide patent, which was the sole and essential means which enabled the world's gold production to soar as it did after the 1890's when the cyanide method really got to work on South African gold.

McArthur was a chemist and founder member of the Society of Chemical Industry. The Forrests were two Glasgow medical men who had a Glasgow shop converted into consulting rooms, and to those rooms there was an underground basement where the three of them conducted chemical experiments. McArthur was a chemist of the highest integrity, and he described to me how he would not consider any experiment worthy of further consideration unless he was able to place the recovered gold as gold available to be weighed as such. At this time the chemistry of gold and all its complex salts was not fully and exhaustively worked out, and if hydrogen sulphide did not pick up the gold it is not surprising that McArthur would miss it. McArthur himself described to me how in their treatment with cyanide solution they were aware that they had lost gold from the mineral, but they were not able to obtain it back by any precipitation method then known. It was two years later before their attention was directed to the potential use of zinc, which is now the standard method of recovering gold which has been dissolved by cyanide.

Sir Charles Tennant, who had very considerable interests in the Indian Mysore gold mines, was, of course, very much involved in the breakdown of the alleged Cassel electrolytic process, and he sent down McArthur to investigate the Cassel experiments, and McArthur reported adversely on them. The next step was that the Cassel Gold Extracting Co. obtained the rights of the McArthur–Forrest process and proceeded to develop them. The first full-scale plant was in New Zealand and was a complete success, and then South Africa was tackled. The Cassel people and the South African mines failed to come to agreed terms on the use of the process the result was litigation in which the Cassel people were finally —in 1896—very distinctly the losers. The McArthur–Forrest patent was invalid in South Africa. The losing situation quickly made itself effective all round the world, so that in general the Cassel Co.'s income from royalties quickly melted away. I will spend no more time moralizing on the ingratitude of mankind to industrialists who have contributed great skill in developing technologies—the pressure of events led to a great and effective discovery, the failure to come to agreed rewards led to there being no reward at all, and in the end, although he had been the effective cause of a far-reaching technical and economic revolution, McArthur lived and died with only a modest financial competence. The development of gold-winning techniques owes a great debt to Sir Charles Tennant for the logical and persistent way he stuck to the need to get technical solutions to the various problems that the physical side of the gold business required.

The Cassel Co. were clearly, after the legal defeat in 1896, not going to be able to maintain an existence by supplying tanks and other relatively simple mechanical appliances. There remained, however, a big chemical question cyanide was wanted in industrial quantities which, even in the period 1890–1900, could be seen to be potentially great. Until the rising use of cyanide for mining purposes became a definite factor, it was used industrially only for electro-plating purposes, and the supply came mainly from ferrocyanide, a by-product of the gas industry. The total cyanide world production at that time was estimated at 50 tons per annum. It is at this point that Beilby enters the picture and McArthur fades out.

The method which McArthur, as an executive of the Cassel Gold Extracting Co., attempted to use for the large-scale deliberate manufacture of cyanide was based on barium, and this process met infinite difficulties.

Beilby in the '80's was an Edinburgh chemist who was employed by the Oakbank Oil Co. in mid-Scotland, the basis of which was distilling oil shale to yield oil and ammonium sulphate. Cyanide in small quantities was also obtained in the distillate, and Beilby's consideration led him to believe that if the temperature of distillation was increased the yield of cyanide would be significantly raised, even at the expense of a smaller yield of ammonia The oil company did not agree, and Beilby resigned to devote all his energies to the development of a direct process to manufacture cyanide from potassium carbonate, ammonia and charcoal This process was successful and supplied substantial quantities of cyanide to meet the growing demand for gold solution

Processes for cyanide manufacture were of very general interest to industrial chemists as a whole, and among those who studied the matter was Hamilton Young Castner—a vigorous American who was attracted to Great Britain, as already stated, by the possibility of manufacturing aluminium by a chemical process This failed because an electrolytic process established itself Castner's interest was thus roused in electrolytic processes, and he then studied and was commercially successful with two electrolytic processes, the electrolysis of brine to give chlorine and caustic soda and the electrolysis of anhydrous caustic soda to yield metallic sodium Castner and his colleagues were able to show that the use of metallic sodium plus charcoal plus ammonia could yield a very pure sodium cyanide which had many advantages over the Beilby potassium carbonate process But Beilby was a wise and shrewd technologist, he saw quicker than anyone, possibly even before anyone else, that the Castner process was a more economical process than the Beilby one, and so without hesitation the Castner process was installed in the Cassel works and proved to be the basis of the development of the Cyanide Industry The Cassel Gold Extracting Co left the scene and became the Cassel Cyanide Co, and most, if not all, of the cyanide to-day in Britain is sold as Cassel-brand cyanide

It is not often that the name of a man who tried to develop a bogus process finds a permanent place in an industry of considerable economic importance—for that is what I think we can describe cyanide manufacture as to-day Different ores require markedly different quantities of cyanide per ton of ore treated, thus Rand ores are low in cyanide demand per ton of gold, while Canadian ores, I believe, require more than ten times the amount used in South Africa In a paper which I gave some fifteen years ago I made an estimate of 75,000 tons per annum of sodium cyanide made by the Castner process for gold extraction purposes, and so far as I am concerned, this estimate, or something of this order, holds to-day, and that does not take into account various other industrial uses of cyanide, such as manufacture of dyes, case-hardening and pest control work, which have all sprung up largely because of the availability of cyanide following the economic need which was caused by the desire to win quantities of gold by steady industrial methods

This sequence of increased demand for gold for general industrial and commercial reasons, and the solution to that problem found by the very well-founded technological advance in the discovery of the cyanide process, which in its turn brought about a scientifically well-founded addition to the chemical industry, is a story which I believe helps towards the understanding of action and reaction between economics, technology and science

---

RADIO AND THE IONOSPHERE*

By Sir EDWARD APPLETON, G B E, K C B, F R S

Principal and Vice-Chancellor, University of Edinburgh

THE ionosphere is a realm of the universe which was both invented and discovered The physicist Balfour Stewart, for example, invented the ionosphere, in 1882, as the hypothetical location of an overhead atmospheric system of electrical currents In his own words, he was driven to postulate that the upper atmosphere was an electrical conductor because he could find no other satisfactory explanation of the daily rhythmic changes in the Earth's magnetic field, which had been the subject of much speculation since their discovery, by George Graham, in 1722 A E Kennelly and Oliver Heaviside also invented the ionosphere as an ingredient in their theoretical explanations of Marconi's successful communication by radio, across the Atlantic Ocean, in 1901 However, it was not until 1924 that the existence of the ionosphere was demonstrated by direct radio experiments and its height above the ground determined The methods used for locating the ionosphere would, nowadays, be called frequency-modulation radar and pulse radar

Once the ionosphere had been identified and located it was possible to devise all kinds of radio experiments calculated to disclose its electrical content and its structure Using pulse radar, for example, it was discovered that the ionosphere is a doubly refracting medium, due to the influence of the Earth's permanent magnetic field From a study of echo-doubling it has been possible to identify, by radio means alone, the nature of the particles which confer electrical conductivity on the upper atmosphere Such particles are found to be negatively charged and to have the charge-to-mass ratio of the electron Radio exploration of the ionosphere has therefore been, to a large extent, the determination of the way the electron density varies with height above the point of observation With a sufficiently close network of such exploring stations, distributed over the Earth's surface, it has been possible to derive a global picture of the morphology of the ionosphere and its variations, which, again, has stimulated much theoretical work on upper-atmospheric atomic physics

The determination of the way the electron density varies with height in the ionosphere is usually accomplished by vertical radio sounding leading to the production of an ionogram This is a graphical portrayal of the relation between the equivalent height of reflexion, measured in kilometres, and the exploring radio-frequency, measured in megacycles per second From an ionogram there can be read off the critical penetration frequencies of the various

---

[*] Substance of one of the lectures delivered at King's College, London, on February 5, to mark the centenary of the publication of Clerk Maxwell's papers on electromagnetic radiation The lectures will be published in book form in due course

strata into which it is convenient to divide the ionosphere From such critical penetration frequencies the maximum electron densities of such strata can be calculated using well-known magneto-ionic dispersion formulæ Ionospheric electron densities, when measured by the ionogram method, are found to be in the range of a million electrons per c c A confirmation of such values has, more recently, been derived from rocket sounding flights conducted in the United States

As soon as the method of measuring maximum electron densities—or peak electron densities, as they are sometimes called—had been devised, it was natural to make ionogram studies of the way the two main strata of the ionosphere, the *E*-layer and the *F*-layer, varied with the hour of the day, with the season of the year and with the course of the sunspot cycle There was thus inaugurated the long-term exploration of the ionosphere which has continued, in a steadily expanding fashion, since 1931 to the present day

The earliest ionogram study of the *E*-layer was made at King's College, London, during the year 1931 It was then at once discovered that the peak *E*-layer ionization was subject to a marked solar control, for the electron density was found to increase round about sunrise, to reach a maximum round noon, and to wane at sunset The continuation of such measurements on a routine basis, which was taken over by the Radio Research Station, Slough, showed that the *E*-layer ionization was greater in summer than in winter, a further illustration of solar control However, the same series of measurements led, in due course to the discovery that the peak *E*-layer ionization varied in sympathy with the trend of the sunspot cycle This has led to the conclusion that the solar radiation which causes the *E*-layer, now thought to be X-rays, varies directly with sunspot activity This is in striking contrast with the visible light waves and the heat waves received at ground-level from the Sun, for they do not vary at all with sunspot activity

The discovery of the sunspot-cycle control of *E*-layer ionization at once recalled the suggestion of Balfour Stewart that an upper-atmospheric conducting layer might be the location of the currents responsible for the small changes of the Earth's magnetic field which are to be noted all over the world, especially just before local noon A critical examination of geophysical events during the last two sunspot cycles, made at the University of Edinburgh, has shown that there is a close quantitative parallelism between the magnitudes of the *E*-layer ionization and the small daily changes of the Earth's magnetic field This has afforded strong support to the view that the overhead current system, the existence of which was postulated by Balfour Stewart, is in fact located at the atmospheric level of the *E*-layer

Since the electron density in the *E*-layer does not increase without limit under the influence of solar irradiation, there must be some electron dissipative process concurrently operative Now, undoubtedly, the first thing noted about atomic processes in the *E*-layer was that electrons seemed to disappear far more rapidly than was expected according to the simple theory of radiative recombination between electrons and positively charged atoms The rate of electron disappearance is, in fact, 10,000 times as great as simple theory predicts The recognition of this discrepancy led D R Bates and H S W Massey to propose that recombination in the lower ionosphere takes place by way of the union of an electron and a positively charged molecule, the latter being dissociated in the process The elaboration of this theory of dissociative recombination has proved notably successful in explaining, in quantitative fashion how electron capture-rates vary with height in the atmosphere

Turning to consider the *F*-layer of the ionosphere we may note its special importance from the point of view of practical long-distance radio communication This arises from the fact that it is the most strongly ionized stratum of the ionosphere and therefore reflects the shortest radio waves, and, as simple ionospheric theory demonstrates, the shorter the wave-length the less is the attenuation of the waves during the process of reflexion Because of this importance of the *F*-layer in facilitating short-wave radio communication there has been a practical objective in the study of its global morphology and the variation of that morphology with time The practical objective is that of forecasting the optimum radio wave-length for use in any part of the world at any particular time For this can be done, by way of appropriate calculations, provided we know the maximum electron content of the *F*-layer, and the atmospheric height at which that maximum is reached, for ionospheric conditions along the track of the radio circuit in question

During the Second World War many ionospheric sounding stations were instituted in different parts of the world to serve the needs of the Allied Forces in forecasting optimum wave-lengths for long-distance transmission by short waves However, when the War was over and practical requirements had less urgent priority, it was possible to subject these war-time measurements to more leisurely scientific study At once a remarkable feature of the *F*-layer was discovered, in that its peak ionization was found to be subject to a geomagnetic control The morphology of the *F*-layer maximum is, in fact, more closely associated with magnetic latitude than with geographical latitude Actually, it is thought that the electrons and ions in the *F*-layer are initially produced by electromagnetic solar radiations and therefore, to that extent, there is a control according to geographical latitude But it is now generally accepted that such ionization does not remain where it is originally produced, and soon moves, possibly by diffusion or electric drift, into what may be called its geomagnetic position

Much attention is at present being given to the theoretical study of the *F*-layer of the ionosphere, but it is clear that more experimental information is needed particularly about that part of the *F*-layer which exists above the level of its peak Such information is steadily being acquired, by rocket and satellite studies, as well as by other means, largely under American auspices One notable discovery has been made by studying the orbital decelerations of satellites due to atmospheric drag, namely, that there are very large variations of the actual air density and temperature at high atmospheric levels Such variations are found to be subject to diurnal, seasonal and sunspot-cycle control Undoubtedly, these remarkable air density variations at high levels must have a profound effect in determining the variations in *F*-layer morphology and so probably will provide the clue for explaining many of the *F*-layer anomalies previously identified—and for which no satisfactory theoretical explanation has been, so far, forthcoming

EUGENICS IN EVOLUTIONARY PERSPECTIVE*

By Sir JULIAN HUXLEY, F.R.S.

THE 'knowledge explosion' since Darwin has given us a new evolutionary vision, in the perspective of which eugenics must be viewed. Man, we now know, has become the latest dominant type to be produced in the nearly three billion years of biological evolution. Barring accidents due to his own stupidity, he has at least an equal space of time before him. He owes his dominant position to the development of a new mechanism of inheritance and transformation, operating by cumulative transmission of experience. With his arrival on the scene, evolution has passed from its biological to its very different psychosocial phase. His destiny is necessarily that of directing (or misdirecting) the future course of evolution on this planet.

In spite of his astonishing improvement, brought about by natural selection in the past, from a sub-microscopic to a cellular, a metazoan, a vertebrate and a hominid stage, he is still very imperfect as a psychosocial type of organism, and is capable of great genetic improvement. The aim of eugenics is to effect such improvement of the human type.

Some critics of the eugenic movement assert that large-scale eugenic improvement is impossible until we have a much more detailed scientific knowledge of human genetics. This is not so. Relying on our knowledge of the course of pre-human evolution and present-day species-formation, and on the results of pre-scientific animal and plant breeding, we can be sure that the general level of human performance and genetic capacity could be markedly raised, simply by encouraging the differential reproduction of human beings exhibiting generally desirable characteristics such as health, physical beauty, manual dexterity, longevity, athletic ability, intelligence, general mental ability, mathematical, aesthetic and other special aptitudes, and capacity for leadership and for co-operative effort. What is more, since outstanding individuals are a major source of social efficiency and cultural advance, the level of human performance could be markedly raised by the production of quite a small additional number of men and women exceptionally endowed with outstanding mental qualities.

Others claim that large-scale eugenic improvement could only be brought about by rigorous authoritarian methods. This again is not true. Experience shows that radical social changes can occur by consent, and can be effected by a combination of persuasion and good leadership, especially when the level of general education is high. Accordingly, better education, notably concerning biology, reproductive physiology, genetics and evolution, is needed before we can embark on a eugenic programme. Another prerequisite for successful eugenics is the control of the present excessive rate of increase in population.

Negative eugenics aims at reducing the frequency and preventing the spread of genetic defects due to undesirable genes or gene-combinations, including such conditions as hæmophilia, schizophrenia, proneness to diabetes, various types of mental defect, including very low intelligence quotient, and certain temperamental deficiencies, and, of course, the great majority of radiation-induced mutational defects. The need for negative eugenics has become urgent in recent years, partly because of atomic and nuclear explosions and of the increase in man-made radiation, partly owing to the differential increase of lower-income groups, the effects of which cannot be eugenic and are probably dysgenic, but mainly owing to the progress of medicine, public health and social welfare, which permits the survival and reproduction of many types who would have died young in earlier periods.

We can be sure that early man's social organization, in the form of small competing groups, would have encouraged genetic improvement of characters like intelligence, manual dexterity and ability to communicate and to co-operate. To-day, however, with the increase in size and reduction in number of social groups, inter-group selection has become much less effective, intra-group co-operation has permitted the survival of genetically defective types and the spread of undesirable mutations, and there is every prospect of general genetic retrogression unless we amend our social organization. Accordingly, for negative eugenics to succeed, medical and public health services must be enlarged to include family planning and eugenic advisory services and the regulation of population and reproduction in general. Taxation and family allowance systems should be modified to discourage excessive reproduction.

In general, eugenists must not disregard the environment, but must help to plan social environments which will promote genetic improvement as well as cultural advance. Simpler methods of birth-control are needed, whether oral or by injection, or by voluntary sterilization. Especially in combination with sterilization, artificial insemination by sperm from a non-defective individual (A.I.D.) is strongly indicated.

Positive eugenics is more inspiring but also more difficult. It aims at the progressive genetic improvement of the human species, in full consciousness that the possibilities of such improvement are virtually unlimited. It does not aim at the creation of a single uniform breed of man, but at a diversity of excellence, based on a general raising of the level of desirable genetic capacities, coupled with the provision of fuller outlets for their effective exercise. It does not envisage the dogmatic application of rigid rules as to desirable and undesirable qualities, nor the employment of dictatorial or authoritarian methods. It prefers to rely on education, persuasion and intelligent leadership, acting on the good will and good sense of humanity at large.

To succeed, positive eugenics can no longer rely on such slow and marginal methods as the financial or social encouragement of the reproduction of 'superior' couples. It must yield obvious and reasonably rapid results.

Luckily the necessary techniques are already available, or can be readily perfected. These are (1) safe and simple methods of conception-control or prevention, (2) artificial insemination from donor males (A I D), and (3) the preservation of mammalian sperm for indefinite periods by deep-freezing Furthermore, it can only be a matter of time before we arrive at the complementary method (4) of assuring a long-term supply of female gametes by deep-freezing immature female germ-cells

---

* Substance of the Galton Lecture given before the Eugenics Society on June 6.

The first step towards large-scale positive eugenics would be the decision by a few enlightened couples to have recourse to what has been called eutelegenesis—A I D by means of sperm from some admired donor to 'father' their children Deep-freezing of sperm will make it possible to utilize a smaller number of more outstanding donors as parents, even after their bodily death

Doubtless this would be met with abuse and with various legal difficulties at the outset but the certain success of the experiment, in the shape of outstanding and happy children, would soon be decisive in inducing an increasing number of couples to adopt similar methods, and eventually in making it an accepted and approved practice

Meanwhile, the immediate provision of shelters for banks of deep-frozen sperm is desirable as a protection against the genetic effects of atomic blast and fall-out, and would, of course, facilitate positive eugenics by eutelegenesis

It is frequently objected that such practices will never be generally adopted, as they run counter to deep-seated human 'instincts' I do not believe this Certainly there will at first be widespread and often violent opposition, just as there has been to birth-control and is now to legal reforms concerning homosexuality But the opposition will spring from tradition and prejudice, not from instinct Human instincts are few and very plastic During human history, the operation of the sexual instinct has been modified in a number of surprising ways There has been acceptance of polygamy, polyandry and monogamy, with or without divorce, there has been approval of clerical celibacy and female virginity there has been tolerance of man's promiscuity, or pre-nuptial sexual partnership and of male indulgence I see nothing against an eventual acceptance and approval of eutelegenesis, in the shape of vicarious parenthood by outstanding donors After all, it would have the highest ethical motivations, in promoting the welfare and fulfilment of the children, of society and of the species

So we return to the evolutionary perspective Once it is grasped that man's destiny is to direct the future evolution of himself and his planet, the fuller realization of desirable possibilities will become man's strongest ethical motive To achieve this, he must improve not only his social system but also his genetic endowment This means eugenics and it is inevitable that eugenics will eventually play a key part in the future world society

Meanwhile, the immediate tasks of the eugenic movement must include much increased research on human heredity and reproduction and their control, together with the promotion of better education in the facts and implications of evolutionary and social biology, and of public understanding of the practical possibility, the social value, and the ethical importance of positive eugenics

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

RETIREMENT OF SIR CHARLES HARINGTON, K.B E., F.R S.

On July 31, Sir Charles Harington retires from the directorship of the National Institute for Medical Research after having held this important post for twenty years At the beginning of his directorship the Institute had a scientific staff of thirty-five and was housed in an old converted hospital at Hampstead, at the end it had a scientific staff of some 125 and, since 1950, had been accommodated in the new Institute at Mill Hill as well as in the original building at Hampstead

Sir Charles received his scientific education at Cambridge, and then, in 1920, went as research assistant to the Department of Therapeutics in Edinburgh Two years later he became lecturer-in-charge of the Pathological Chemistry Department at University College Hospital Medical School and successively reader in 1928, and professor in 1931, with which post, from 1937, he combined the directorship of the Graham Research Laboratories In 1931 he was elected to the Royal Society, being its Croonian Lecturer and its Royal Medallist in 1944 During this period he rendered outstanding service as editor of the *Biochemical Journal* and later played an important part in founding the International Union of Biochemistry

In respect of his personal contributions to research, Sir Charles's name will always be identified with his elucidation of the structure of thyroxine, and later, in conjunction with Barger, the synthesis of this compound in its racemic form Out of this developed an impressive mass of work on other iodinated compounds and the biochemistry of the thyroid gland, which introduced a new dimension to the biochemistry of the endocrine glands But his interests were not confined to those fields A second line led to the synthesis of glutathione, which was important not only in itself but also because of the new synthetic methods for peptides that he introduced In a third, he pioneered the field of synthetic immunochemistry, preparing protein complexes of tyrosine, thyroxine and aspirin and investigating their biological and immunological behaviour Most of this work took place before the outbreak of the Second World War, and later, with his increasing responsibilities, the opportunity for Sir Charles to work with his own hands lessened The influence, however, of his early interests in the chemical approach to biology was reflected in the encouragement and development of related work at the National Institute for Medical Research

In the second period of his career, Sir Charles Harington's contributions to the advancement of scientific knowledge centred on his directorship of the National Institute By personality and experience he was admirably equipped for this task. Even before he became director the breadth of his knowledge on medical and biological research was impressive, and this great ability to assess the importance and potential value of particular research programmes became even greater while he was in charge of this large Institute with its many and varied activities Combined with this was exceptional administrative ability and a capacity to take responsibility and objective decisions These attributes, although essential to a man in such a post, would not, in themselves, have been enough To have their full effect it was necessary for them to be combined with an ability to win confidence not only as a scientist but also as a person There must to-day be many research workers who have occasion to thank him for his help and advice while they were in their formative years It was Harington's intellectual integrity, his unshrinking but generous capacity to deal with a case on its merits, and his willingness to take endless trouble not only on scientific but also personal matters, that accounted for the value that was placed on his opinion and the frequency with which his advice was sought—and accepted—both by his staff and by outside bodies

The dilemma that faces any director of a large research institution is that of ensuring a synthesis of interests while preserving the intellectual initiative of individuals Failure in one direction leads to the institution becoming merely a collection of isolated individual sub-departments, failure in the other to a stereotyped team of deteriorating quality The responsibility for resolving this dilemma rests on the director Its solution lies in wide scientific knowledge and ability and a capacity for objective judgment that commands confidence outside the range of the director's personal experience

It was inevitable that Sir Charles Harington's services should have been sought in increasingly wide fields Throughout his directorship he had been very aware of the need to integrate research being undertaken by a body like the Medical Research Council with that done in the universities and by the practising profession It was, therefore, particularly appropriate that he should be chairman of the Council of University College Hospital Medical School and take a prominent part in the work of the North-West Metropolitan Regional Hospital Board In the day-to-day application of medical and related biological research to practical problems his services are too numerous to mention

It will be a source of gratification that, on his retirement, Sir Charles's services to medical research will not be lost He will continue in his relationship to the Medical Research Council as consultant adviser to the Council's secretary

[As announced in *Nature* of July 30, 1960 (p 374), Sir Charles is to be succeeded as director of the National Institute for Medical Research by Prof. P B Medawar, Jodrell professor of zoology and comparative anatomy in University College (University of London) An appreciation of Prof Medawar's scientific work was published in *Nature* of September 17, 1960 (p 991)]

NEWS and VIEWS

Industrial Research Fellows

The Institution of Chemical Engineers has appointed two Industrial Research Fellows, Dr J R Bourne and Mr R Jackson These appointments follow the first report of the Exploratory Committee of the Institution of Chemical Engineers on Chemical Engineering Research which was published in *The Chemical Engineer* in April 1962 (see also p 209 of this issue) In that report, the Exploratory Committee recommended that a number of investigators, to be called Industrial Research Fellows, should be appointed, each to report on one specific field Each Fellow so appointed is to establish what are the real industrial problems, what additions to our knowledge might mitigate these problems and what programme of fundamental research might produce the knowledge required

Dr Bourne, who is a member of the chemical engineering staff at the University of Nottingham, is concerned with the mixing and agitation of non-Newtonian fluids, powders and pastes, and Mr Jackson, who is at present working in the chemical engineering laboratories of the University of Edinburgh and Heriot-Watt College, is to investigate the field of formation and coalescence of drops and bubbles in liquid systems It is estimated that the Industrial Research Fellows will require from six months to one year to complete their task and produce a report The report may be used as the primary agenda for a working party in the field and/or it may be published by the Institution in order to stimulate individual research workers and sponsors Alternatively it might form the basis of a co-ordinated scheme of research Further information can be obtained from the general secretary, the Institution of Chemical Engineers, 16, Belgrave Square, London, S W 1.

Mental Health at Bristol : Prof. D. Russell Davis

The new Department of Mental Health in the University of Bristol has been established out of private endowment Dr D Russell Davis, the newly appointed professor and head of the Department, will be particularly welcomed His teaching and research experience as reader in medical psychology and director of the Medical Psychology Laboratory in the University of Cambridge will find appropriate fields for development in the University of Bristol and in the United Bristol Hospitals Undergraduate teaching in clinical psychiatry will be increased and closely co-ordinated with other clinical departments in the Medical School A fully equipped unit has been prepared in the Bristol Royal Infirmary so that close functional relationship shall exist with the rest of the hospital and give medical students ample opportunities to pursue the study of the physical and mental aspects of illness and disease A unit has been provided in a nearby Regional Board Hospital for the care and study of mental illness requiring longer periods of hospital care Dr Russell Davis will develop research into the various aspects of mental health, including the ætiology of mental disease on which community and social factors may have an important bearing Opportunities will arise to encourage and develop co-operation between the University and the Local Authorities and the South-Western Regional Hospital Board in connexion with the Mental Health Services In this newly established chair and Department, the University is responding to a long-felt need to reinforce and extend the range of research and teaching in the Medical School and to contribute towards the promotion of mental health and the understanding of mental illness in the community throughout the south-western region of Britain

The Vernon Prize of the National Institute of Industrial Psychology : Prof H Kay

Prof H Kay, professor of psychology at the University of Sheffield, has been awarded the Vernon Prize of the National Institute of Industrial Psychology for his research into industrial training, which has included the use of teaching machines The Prize, founded by the late Dr H M Vernon, of the Industrial Health Research Board, is awarded in alternate years to the British investigator under forty-five who, in the opinion of the Institute, has done the most valuable research work in industrial psychology and physiology Between 1948 and 1951, Prof Kay worked with the Nuffield Research Unit at Cambridge on problems of ageing and also went as psychologist on the Naval Arctic Expedition of 1949 From 1951 until 1959 he was lecturer in experimental psychology in the University of Oxford, but spent a year on research into ageing at the National Institute of Health in Washington, D C His psychological work at Sheffield, where he has been professor since 1960, has been financed partly by the Department of Scientific and Industrial Research

Science in Parliament.

The Royal Society Research Professorships

In a written answer in the House of Lords on June 28, the Minister for Science, Lord Hailsham, stated that the President of the Royal Society had proposed to the Chancellor of the Exchequer that the Society should establish, with Exchequer support and with the approval of the universities concerned, a number of research professorships in British universities The purpose of this scheme would be to meet a need, not at present covered, to provide opportunity for research scientists who are worthy of appointment to a chair but for whom one is not available because they work in a borderline field or in one in which scientific developments are exceptionally rapid, or for similar reasons Lord Hailsham stated that the Government had agreed to provide further direct financial support to the Royal Society to enable them to sponsor the creation of five such professorships, and it was hoped that the first appointments would be made early in 1963 The conditions of tenure would be settled with the universities concerned It was intended that the grant-in-aid to the Royal Society for 1963–64 should contain provision for a new grant covering the salaries of the professors and their immediately supporting staff, and that the scientific investigations grant to the Royal Society should be increased to provide the necessary equipment The cost of this scheme was expected to be about £35,000 next year and £44,000 in the first full year of its operation

Emigration and Immigration of Scientists

In a written answer in the House of Commons on July 2, the Parliamentary Secretary of Science, Mr D Freeth, stated that the Committee on Scientific Manpower had made an estimate (published in Cmnd 1490) based on general population statistics of the total number of scientists who left the United Kingdom annually up to 1959 Figures for Commonwealth citizens travelling by long sea routes only were available up to 1961, and Mr Freeth gave the following figures physicists—emigrants, 1959, 72, 1960, 64, 1961, 101, immigrants, 1959, 34, 1960, 40, 1961, 58 . for chemists, the corresponding figures are —emigrants, 232, 246, 282, immigrants, 176, 208, 161 for biologists—emigrants, 56, 50, 67, immigrants, 48, 32, 41 for mathematicians—emigrants, 8, 8, 12, immigrants, 8, 8, 8 for other scientists—emigrants, 192, 220, 238, immigrants, 140, 154, 155

Education Research in Scotland

In a written answer in the House of Commons on June 29, the Secretary of State for Scotland, Mr J Maclay, stated that Exchequer grants to the Scottish Council for Research in Education were expected to be about £5,000 in the current financial year, compared with £3,000 last year New projects which the Council had recently decided to undertake covered studies in teaching mathematics and of teaching by television His Department had also suggested to the Council investigations of the age of transfer of pupils from primary to secondary education and the use of attainment tests, the optimum size of class and of school, and of the validity of examinations other than the traditional external written examinations and the comparability of examinations in various subjects

Production of Enriched Uranium

In reply to a question in the House of Lords on June 27, the Minister for Science, Lord Hailsham, said that supplies of enriched uranium available for the United Kingdom production were now such as to permit some reduction in the output of the Atomic Energy Authority's plant at Capenhurst Supplies were fully adequate for the present nuclear deterrent policy, which had not changed, and Lord Hailsham said they were also adequate for years to come in view of possible changes of requirements of the civil nuclear energy programme The numbers employed at the Capenhurst plant, which started operations in 1953, would fall by some 500 by about the end of this year and some redundancy would be unavoidable, although some of the reductions would be achieved by wastage and redeployment The greatest possible warning would be given to those concerned and every effort made to assist them in finding alternative employment The Authority would immediately discuss these matters with the staff associations and trade unions concerned

The *Telstar* Communications Satellite

The communications satellite *Telstar* was successfully launched from Cape Canaveral, Florida, at 08 35 U T on July 10 by a *Thor-Delta* rocket vehicle The satellite, which is designated 1962αε1, was placed in an orbit inclined at 44 8° to the equator, with an orbital period of 157 8 min Initially the height above the Earth varied between 950 and 5,640 km, with the apogee about 10° south of the equator when the satellite was going north the apogee is moving northwards round the orbit at a rate of about 2 degrees per day, so that the satellite will be well placed for communication in the northern hemisphere during the next few weeks The satellite weighs 81 kg (178 lb) and is roughly spherical in shape, except that it has 72 facets, 60 of which carry solar cells

Its diameter is 86 cm (34 in) *Telstar* is an active communications satellite—designed to amplify and re-transmit the signals sent to it—and has operated with notable success The first trans-Atlantic television pictures by satellite were transmitted from the station at Andover, Maine, and received at Goonhilly Down, Cornwall, and Lannion, Brittany, on the sixth revolution of the satellite, within 16 hr of launch

Tenth Pugwash Conference

FURTHER to the announcement of the tenth Pugwash Conference to be held in London during September 3–7, which appeared on p 126 of the July 14 issue of *Nature*, the following information has been received

British participants at the Conference will include Sir John Cockcroft, Master of Churchill College, Cambridge, Sir Howard Florey, Master of Queen's College, Oxford, and president of the Royal Society, Sir Julian Huxley, Lord Russell, Sir Charles Snow, and Sir George Thomson, Master of Corpus Christi College, Cambridge The chairman at the opening session of the conference on September 3 will be Sir Nevill Mott, Master of Caius College, Cambridge, and director of the Cavendish Laboratory Among Russians attending the conference may be included Academician Blagonravov, head of the Russian programme of space research, Prof Emelyanov, head of the department responsible for atomic research in the Soviet Union and Russian delegate to the International Atomic Energy Agency in Vienna, I V Federov, secretary of the Moscow Academy of Sciences and at one time the leader of the Russian delegation to the test-ban talks at Geneva, Academicians N Semenov and I Tamm, Nobel prizewinners in chemistry and physics, and Academician A V Topchiev, executive vice-president of the Moscow Academy of Sciences The group from the United States will include Dr D G Brennan, president of the Hudson Institute of New York, and an adviser to the U S Government on defence, Prof Margaret Mead, the anthropologist, Dr J Oppenheimer, director of the Institute for Advanced Study at Princeton and once head of the Los Alamos laboratory of the Atomic Energy Commission, Dr Linus Pauling, Dr Alfred Sabin, and Dr Victor Weisskopf, at present the director of the European Centre for Nuclear Research (CERN) at Geneva

A discussion is to be included in the programme of the Conference of the suggestion that West Berlin should be made the site of an international centre for scientific research

The Journal of Catalysis

THE phenomena of new journals devoted to a single aspect of a science or technology have been of frequent occurrence in the past few years While the prospect of the increasing number of publications one could reasonably be expected to have to scan has become somewhat alarming, it is nevertheless of great value to specialists to have available journals specific to their own field of work It is on such grounds that one can welcome the new *Journal of Catalysis*, edited by J H de Boer and P W Selwood and published by Academic Press (1, No 1, March 1962 Pp 92 New York and London Academic Press, Inc , 1962 Vol 1 (6 issues), 1962 18 dollars) The importance of the subject is one that merits this kind of treatment, but it is to be hoped that the editors will be able to encourage in their journal the publication of relevant papers on surface and solid-state properties, for it seems to be generally true that the sophistication of kinetic studies in catalytic processes has rarely been matched or accompanied by equivalently advanced investigations of the surface structures of the catalyst It would be of great value if specialists in these fields should consider the new *Journal* a suitable medium for the publication of particularly relevant papers in these fields and in heterogeneous processes in general

Bulletin of the International Computation Centre

THE first number of the *I C C Bulletin* has just appeared This continues the functions performed by the Bulletin of the Provisional International Computation Centre (*PICC, Bulletin*), and, in addition, is to act as the organ of the International Federation of Information Processing (IFIP) and will contain reports of the committees of that body (1, No 1 (April 1962) Pp vi + 78 Supplement Repertory of Computation Laboratories Pp 18 Rome International Computation Centre, 1962) In addition to a new set of loose-leaf sheets describing the equipment and facilities of various computer laboratories the latest issue contains an interesting paper, by Prof L Collatz, on the applications of functional analysis to numerical calculation An article on teaching machines and their simulation by a digital computer gives a picture of an automatic classroom of the future, which goes beyond the usual ideas of elementary rote instruction to a view of the way in which teaching administrators can be educated It is an interesting and controversial essay Among the descriptions of new machines and equipment is one of the 'IBM 1301' disk storage unit, its capacity of up to 280 million alpha-numeric symbols with a maximum access time of 0 18 sec is likely to have important implications in the field of information storage and retrieval

European Atomic Energy Research

THE last three issues of *Atom*, the monthly information bulletin of the Atomic Energy Authority, contain some articles of exceptional interest The April issue reports Sir Leonard Owen's re-examination of nuclear power costs and Sir Roger Makin's address to the Institution of Chemical Engineers on nuclear energy in 1962 The May issue includes a long article by V W Eldred and K Saddington describing the post-irradiation examination facilities at Windscale works, while the June issue contains a paper by J A. Williams and P C Davidge of an effluent at Windscale and the effect of the civil power programme given to the British Nuclear Energy Society It also includes a report by Dr M L Smith on the symposium organized by the Central Treaty Organization Institute of Nuclear Science on the role of science in the development of natural resources with particular reference to Iran, Pakistan and Turkey (the Central Treaty Organization countries)

Lasers

ONE of the outstanding technological developments of the second half of the twentieth century is undoubtedly the use of stimulated emission for coherent generation of micro-wave radiation and light The maser has been rapidly followed by the laser (or optical maser), and during the past two years the published literature on the latter has grown to vast proportions The Central Library (*TIL*3) of the Ministry of Aviation has accordingly performed a most valuable service to those interested in this rapidly growing field of research by issuing a bibliography with brief abstracts covering the period December 1958–May 1962 (Bibliographical Series, No 4 Lasers Compiled by K J Spencer Pp i+39 London Ministry of Aviation, 1962) The abstracts are short, but give an indication of the contents of most papers Some indication of the rate of growth of the subject may be gathered from the number of references quoted 1958, 2, 1959, 10, 1960, 19, 1961, 168, 1962 (January–May), 129 About eighty more references from symposia proceedings are also given The references deal not only with the physics of laser action, but also with their achieved, proposed and dreamed of applications

Foundations of a Flora

MANY of those who have rightly admired Sir Joseph Dalton Hooker's great achievement in producing his *Flora Tasmaniae* (London, 1860), with its important introductory essay on plant geography and its bearing on evolutionary fact and theory, may perhaps not have appreciated how much he was helped by a long series of reports and collections of specimens made to his father, Sir William Jackson Hooker, and to himself, by local Tasmanian naturalists and collectors In fact, as it now appears, he received an astonishing amount of information from local sources T E Burns and J R Skemp, and the Queen Victoria Museum, Launceston, Tasmania, are therefore to be congratulated on having made available some notable correspondence between R C Gunn—one of the great Tasmanian travellers and naturalists—R W Lawrence, Jorgen Jorgenson, Sir John Franklin and other botanists, and Sir William Jackson Hooker (one-time Regius professor of botany in the University of Glasgow and, later, director of the Royal Botanic Gardens, Kew), covering the period 1827–49 Not everyone has a taste for these by-ways in the history of botany, but for those who wish to understand something of the pioneering work that made possible the compilation of an important Flora, and of the cumulative experience that afforded substantial and timely support to exponents of evolution at a critical time, a perusal of the present volume is likely to prove rewarding (*Records of the Queen Victoria Museum, Launceston* (New Series) No 14 Pp xix+142 Launceston, Tasmania Queen Victoria Museum, 1961)

Influence of Mental Tension on Diabetes Mellitus

HEREDITY plays an essential part in the development of diabetes mellitus States of mental tension, no matter how severe, cannot cause diabetes without an inherited predisposition to the disease Mental stress can result in the appearance of overt diabetes among previously latent diabetics It can also aggravate existing diabetes mellitus temporarily, and sometimes permanently, especially in states of prolonged mental tension This is so much the case that, in mild cases previously controlled by diet alone, acidosis and even pre-coma may result In eight cases described by Dr S Sukiennik, Central Clinic, "Zamenhoff", Tel Aviv, diabetes appeared in four following severe mental tension (*Dapim Refuim*, 21, No 2, February 1962) As the nervous tension decreased, the diabetes regressed to its latent state or became mild and stabilized again. In the other cases, diabetes grew worse during mental stress, being temporary so long as the stress was temporary, but persisting while the stress continued States of mental stress cause the over-secretion of steroids of the 11-oxy-steroid group These substances lead to excessive catabolism of proteins, and to the overproduction of glucose by means of gluconeogenesis in the liver They also result in the decreased utilization of carbohydrates by the tissues, as well as changes in electrolyte balance With steroid therapy, diabetes becomes manifest only among those with an inherited predisposition to the disease Glucose tolerance tests with steroids show that even the temporary increase of steroids can result in temporary changes in carbohydrate metabolism This is seen also after excitement or following fits of anger in diabetes

The Royal Society and Nuffield Foundation Commonwealth Bursaries Scheme: Awards

AWARDS under the Royal Society and Nuffield Foundation Commonwealth Bursaries Scheme have been made as follows Mr J K Coulter, head of soil research and survey section, regional research centre, University College of the West Indies, to assist him to study the work on classification and fertility of tropical and sub-tropical soils being carried out by the Commonwealth Scientific and Industrial Research Organization in Australia, from December 1962 to February 1963, Dr A T Cowie, Department of Physiology, National Institute for Research in Dairying, Reading, to assist him to collaborate in research on the physiology of lactation at the Department of Animal Husbandry, University of Sydney, from April to June 1963, Dr E J Denton, principal scientific officer, Marine Biological Association Laboratory, Plymouth, to enable him to visit New Zealand and New Caledonia and related islands in order to study marine animals in environments different from those found in the English Channel and North Atlantic, for 3–4 months from mid-October 1962, Mr J R Dunstone, lecturer in biochemistry, University of Queensland, to enable him to pursue research into the physical aspects of biologically important mucopolysaccharides at the Lister Institute in 1963, Prof J F Heard, professor of astronomy and director of the David Dunlap Observatory, University of Toronto, principally to assist him to study methods of stellar spectroscopy at other Commonwealth observatories, including Mount Stromlo, for about 2 months during 1963, Dr J I Hubbard, Department of Physiology, Australian National University, Canberra, to enable him to study electron microscopy techniques at University College, London, from September 1962 for 5–6 months, Mr R A Jarvis, member of Soil Survey of England and Wales, to enable him to visit New Zealand at the end of 1962 for 3 months in order to make a critical comparison of red and yellow podzolic soils occurring there with the relevant English soils, Dr T F Neales, senior lecturer in botany, University of Melbourne, to enable him to study techniques in the culture of excised plant roots at the University College of Swansea, in 1963, Prof E L. Yates, professor of physics, University College of Rhodesia and Nyasaland, to enable him to discuss problems of solid-state physics at Melbourne, from May until September 1962

Physiology and Psychology in Arid Lands

A SYMPOSIUM on "Environmental Physiology and Psychology in Arid Conditions", organized by the United Nations Educational, Scientific and Cultural

Organization, is to be held in India during August 27–September 1 The programme will include discussions on medical climatology of arid zones, physiological anthropology, comparative physiology of arid lands, nutrition and heat, water and electrolytes, neurophysiology of heat exposure, significance of solar radiation in the heat balance, performance and comfort standards, psychological aspects of life in hot climates Further information can be obtained from the Department of Natural Sciences, Unesco, Place de Fontenoy, Paris 7e

The Night Sky in August

Full moon occurs on Aug 15d 20h 10m U T and new moon on Aug 30d 03h 09m The following conjunctions with the Moon take place Aug 4d 08h, Venus 4° S , Aug 14d 19h, Saturn 0 9° S , Aug 16d 23h, Jupiter 1° N , Aldebaran 0 9° S , Aug 24d 22h, Mars 3° N In addition to these conjunctions with the Moon, Mercury is in conjunction with Regulus on Aug 10d 05h, Mercury being 1 1° N , and Venus with Spica on Aug 31d 02h, Venus being 0 02° S There is a penumbral eclipse of the Moon on August 15, partly visible at Greenwich, where moonrise is at 19h 25m, mid-eclipse is at 19h 57m and eclipse ends at 21h 39m, and the penumbral magnitude is 0 62 Mercury is too close to the Sun for observation Venus is an evening star, visible low in the west after sunset and setting little more than an hour after the Sun Mars rises at 0h 10m, 23h 45m and 23h 30m on Aug 1, 15 and 31, respectively. It is at a distance of 164 million miles on August 15, and its stellar magnitude is +1 3 Jupiter rises shortly after sunset, and remains above the horizon all night It is in Aquarius, its stellar magnitude is −2 4 and its distance from the Earth on August 15 is 374 million miles Saturn is in Capricornus, setting at 4h 30m, 3h 25m and 2h 15m at the beginning, middle and end of the month, respectively Its stellar magnitude is +0 4 and its distance from the Earth in the middle of the month is 834 million miles Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich Aug 9d 21h 16 0m, 49 Lib (*D*), Aug 22d 00h 08 9m, 5 Tau (*R*), Aug 23d 01h 14 9m, 75 Tau (*R*), Aug 23d 01h 51 5m, 264 B Tau (*R*) *D* and *R* refer to disappearance and reappearance, respectively The Perseid meteors are active during the first half of the month, but conditions are rather unfavourable for observation

Announcements

Prof E B Chain, professor of biochemistry at the Imperial College of Science and Technology, has been elected an associate member of the French Academy of Science

Prof J E Harris, professor of zoology in the University of Bristol, has been elected a member of the Agricultural Research Council in succession to Prof P B Medawar, who retires from the Council on September 16

Mr J E C Bailey has been elected president of the British Scientific Instrument Research Association Mr Bailey, chairman and managing director of Baird and Tatlock (London), Ltd, Hopkin and Williams, Ltd, and W B Nicholson (Scientific Instruments), Ltd, and a director of Derbyshire Stone, Ltd, has for many years been prominent in the scientific instrument industry both as president of the Scientific Instrument Manufacturers Association during 1945–50, and since 1952 as chairman of the British Scientific Instrument Research Association

The Challenger Society is prepared to make small grants for research in marine biology or oceanography at a recognized laboratory during the year July 1962–63 Applications, accompanied by details of the proposed research, should reach the Honorary Secretary, Challenger Society, National Institute of Oceanography, Wormley, Godalming, Surrey, not later than August 4

A conference on "Gasification Processes", arranged jointly by the Institution of Gas Engineers and the Institute of Fuel, will be held at Hastings during September 10–14 Further information can be obtained from the Institute of Fuel, 18 Devonshire Street, Portland Place, London, W 1

The second congress of the International Council for Building Research on "The Influence of Changing Requirements and Developments in Materials and Components on Design and Construction" will be held in Cambridge during September 5–11 Further information can be obtained from the Organizing Secretary, CIB Congress 1962, Building Research Station, Garston, Watford, Herts

The third national conference of the British Computer Society will be held in Cardiff during September 4–7 Topics to be covered include business data processing, industrial data processing, data origination and transmission, developments in equipment Further information can be obtained from G J Morris, British Computer Society Conference Publicity Committee, I C T, Ltd, Putney Bridge House, London, S W 6

An international symposium on "Information Theory", organized by the Benelux Section of the Institute of Radio Engineers and the Belgian Society of Telecommunication and Electronics Engineers and sponsored by the Professional Group on Information Theory of the Institute of Radio Engineers, will be held in Brussels during September 3–7 Further information can be obtained from the chairman of the Organizing Committee, Dr F L Stumpers, Philips Research Laboratories, Eindhoven

A conference on "Low-Energy Nuclear Physics", sponsored by the Institute of Physics and the Physical Society, will be held at the Atomic Energy Research Establishment, Harwell, during September 12–14 Subjects under discussion will include the nuclear interactions of slow and fast neutrons, nuclear reactions induced by charged particles and γ-rays, nucleon–nucleon interactions, nuclear structure and nuclear models Further information can be obtained from Dr G C Morrison, Nuclear Physics Division, Atomic Energy Research Establishment, Harwell, Didcot, Berks

An international symposium on "Magnetoplasmadynamic Electrical Power Generation", sponsored by the North-Eastern Centre of the Institution of Electrical Engineers in collaboration with the North-Eastern Branch of the Institution of Mechanical Engineers, the North-Eastern Branch of the Institute of Physics and the Physical Society and the University of Durham, will be held at King's College, Newcastle upon Tyne, during September 6–8 Further information can be obtained from the Symposium Secretary, Institution of Electrical Engineers, North-Eastern Centre, c/o C A Parsons and Co, Ltd, Heaton Works, Newcastle upon Tyne, 6

THE MATHEMATICAL ASSOCIATION

THE annual conference of the Mathematical Association, held in London during April, attracted a record attendance This was, perhaps, in keeping with the growth of membership, the figure for which is now the highest in the history of the Association, having reached almost five thousand

Liveliest interest was aroused by the presidential address delivered by Mr J T Combridge, registrar of King's College, London, and by a discussion on the relationship between mathematics and industry

Mr Combridge himself introduced this subject, and major contributions were made by Mr F W Kellaway, principal of the College of Technology, Letchworth, and Mr P L Taylor of Associated Electrical Industries, Ltd Mr Kellaway dealt with the two-way problem of interpreting the needs of industry to mathematicians and explaining the uses of mathematics to industrialists He surveyed the supply of, and demand for, graduate and graduate-equivalent mathematicians and the need for near-graduate qualifications Already the Association had introduced the diploma in mathematics for teachers and intending teachers, the reputation and value of which had quickly become established "It was", said Mr Kellaway, "the duty of the Association to care equally for mathematicians in industry "

Mr Taylor expanded and supported this theme "If we, in this country, do not strive to foster the partnership between science and industry", he said, "we shall surely slip back from the front rank to the second, and the second to the third until we ourselves become an under-developed country Mathematics is central to science as a tool and as a discipline The challenge, therefore, is to produce the increasing numbers of technological mathematicians and mathematical technologists The life-cycle of the mathematician in the past—from school to university and so back to school—is not attractive enough for many young people to-day, when there are so many more interesting things to do in the world The task of members of the Association is to inform themselves of these exciting things and transmit their enthusiasm to pupils

"The second challenge is to determine both the matter and the manner of the teaching that will produce the sort of people that are needed in industry One good way of achieving this is to have some form of society or institute, to which the mathematician working in industry can belong His colleagues in physics, chemistry and the various branches of engineering and technology, all have their appropriate institutions The activities and benefits of these institutions were known to all The pointer to the Mathematical Association was obvious "

Following the discussion, the proposition that the Association should inaugurate a second diploma examination was carried by an overwhelming majority It is likely that the examination would be of a standard requiring part-time study extending over three years beyond General Certificate of Education, advanced-level, attainment Syllabuses would be appropriate to the needs of industry It was clear that a move towards the creation of an institute of mathematics might also be welcomed

In his presidential address Mr Combridge referred to the new outlook on mathematics resulting from the Bourbaki publications, and its effect on the content and orientation of university teaching Some of the newer concepts had applications in commerce and industry In this realm also some quite elementary mathematics was now applicable because of the development of machines able to deal with calculations that had previously been prohibitive

There was a danger that introducing the newer mathematical ideas too early might mean presenting pupils with abstract ideas before they were old enough to do more than cope with numerical applications Nevertheless, the increasing demand for competent users of mathematics was producing pressure on the Association which called for urgent consideration Thought and action in the mathematical world in the United Kingdom were hampered by lack of channels of communication within the Association and between the various mathematical organizations, and there was no one to speak for mathematics as a whole

The Association had not been inactive Its objects, which were "to effect improvements in the teaching of elementary mathematics and its applications, to provide means of intercommunication between mathematical students and teachers for this purpose, and to take such measures as may appear expedient to advance the views of the Association on any question affecting the study and teaching of elementary mathematics and its applications", allowed considerable development, and its appeal was becoming wider

Some acquaintance with the newer outlook on mathematics, and with applications of it and of more elementary mathematics in industry, should make the subject more meaningful for teachers and pupils alike, and thereby reduce the number of children being frightened off mathematics at an early age

The President believed that mathematics would not be endangered by placing itself at the service of the community He propounded the thesis that such action was in accordance with principles that underlie the development of the subject, and that these principles are intrinsic not only in the subject but also in nature itself, so that progress would only be achieved by working in harmony with them The mathematician who demands complete isolation, and the technologist who insists that mathematical development shall be governed by considerations of utility are both extremists who forget that one function of the community is to promote the proper development of each individual in it, and that the individual finds his true development in service to the community The development of mathematics exhibits this truth in action

The concept of mathematics as queen and servant of the sciences is a familiar one It did not imply, however, that pure mathematics is queen and applied mathematics servant Rather are 'queen' and 'servant' two interdependent aspects of mathematical development which are often to be seen in action simultaneously The proper distinction is perhaps the one that Hardy made between 'real mathematics' and 'trivial mathematics' In Egypt or Greece, land measurement and Euclidean geometry may well have developed side by side Centuries later, the theories of Bolyai and Lobatchevsky produced a major advance in abstract thinking, but Riemannian geometry provided Einstein with the tool for a similar advance in mathematical physics This in its turn led to extensive developments in the concepts of parallelism and of affine geometry

Just a century ago Clerk Maxwell, in the College where this address was being given, was formulating for the physical electromagnetic concepts of Faraday the mathematical equations which bear their author's name The development and applications of Fourier's work provided another example of the co-existent roles of queen and servant

So also Dirac introduces his delta function into Fourier theory for mathematical-physical purposes, Schwartz produces the rigorous generalized theory, Temple simplifies it, and Lighthill produces a text-book which might have satisfied Hardy and might even have been classified by him as 'real' mathematics

It is not, however, a question of mathematics alone Mathematics may be entirely an expression of human thought, it may be an objective reality awaiting investigation and discovery, the truth is probably somewhere between But the mathematical world consists of mathematics and mathematicians, and the total of these is something different from the arithmetical sum of the several parts It is not necessary to elevate mathematics to the category of personality, it has not the faculty of responsiveness in the way that human personality has But (as Henri Poincaré, for example, has shown) it does partake of the activities of the subconscious mind It calls for and responds to our questionings just as our body will demand and respond to alternations of exercise, work and rest It is not astonishing therefore to find that principle of simultaneous service and supremacy, which we discern in the development of mathematics, operating in the mathematical world—the world of mathematicians and their mathematics—as a whole

Moreover, this mathematical world is itself an intrinsic part of nature, and so, as a curve on a curved surface is also a curve in the Euclidean sp dimensions in which that surface may be as embedded, the laws of the mathematical wo laws of the nature that is intrinsic to all Progres will be achieved by working with them and not ignoring them The noteworthy feature of mathematical development, the constant interplay of service and supremacy, should also characterize the policy of the Mathematical Association The Association should refuse to give up freedom for itself or for others, the mathematical world must not be allowed to become merely a tool or a slave for the world of materialism But when it has freedom it should not disdain to serve, only those who are free can serve, and there is a service that is perfect freedom, and service—the service of one's neighbour as one's self—brings the intrinsic right to existence, to individuality, to personality, to continual freedom, and to the only kind of sovereignty worth having

Subjects of other papers read at the conference included "Matrices for the Million", by Dr G Matthews, of St Dunstan's College, Catford, and "Radar", by Dr E Eastwood of Marconi's A talk, with demonstrations, on mathematical films by Mr W M Brookes of the University of Southampton was widely acclaimed

At the business meeting Prof V C A Ferraro was elected president for 1962–63 Mr F W Kellaway was re-elected as honorary secretary for the thirteenth year and will serve as general secretary of the Association Miss R K Tobias was elected an honorary secretary in place of Miss W A Cooke tribute to whose services was paid Miss Cooke was elected a vice-president Prof R L Goodstein of the University of Leicester will continue as librarian and editor and Mr W M Brown was re-elected as honorary treasurer A number of posts of honorary assistant secretaries was also established Mr B J F Dorrington, Mr R E Green and Dr E Kerr were elected, Mr Dorrington will also serve as secretary to the Examination Board

VISCO-ELASTICITY AND THE WEISSENBERG RHEOGONIOMETER

THE meeting of the Cambridge Rheology Club held on May 7 was opened by Mr R G King (Farol Research Engineers), who spoke on "Visco-elasticity and the Weissenberg Rheogoniometer" He described the instrument as a rotating cone and plate viscometer which, while measuring viscous behaviour additionally recorded any normal forces which might be produced by a visco-elastic material Thus it was an instrument specifically designed for testing visco-elastic materials The upper cone was free to move about its axis against a torsion bar measuring tangential stress The lower platen was driven and the normal force on it measured From values of tangential stress and normal force the coefficient of viscosity and elastic modulus could be calculated Variations in shear-rate might affect both separately and to a different extent An alternative method of measurement was by oscillation about the vertical axis If the material was completely elastic, the input strain and resultant stress would be in phase, if purely viscous, the phase difference would be 90° Visco-elastic materials would exhibit intermediate phase differences

Mr King described the *R*14 rheogoniometer with particular reference to latest developments The instrument was fitted with two synchronous motors (one for oscillation, one for rotation experiments) each driving one 60-speed gearbox A shear-rate of from 10^{-4} to 4×10^{3} sec $^{-1}$ could be obtained In oscillation experiments a range of frequency from 25 cycles/sec to $25 \times 10^{-5\ 9}$ cycles/sec was available Tangential stress measurements could be taken from 1×10^{2} to $1\ 5 \times 10^{7}$ dynes/cm ^{2}, normal pressure measurements from 2×10^{2} to $2\ 7 \times 10^{6}$ dynes/cm ^{2} A servo system was fitted to maintain a constant gap between the plates during the experiment Five displacement transducers in conjunction with Pendeford multimeters were used for calibration and measurement The test could be conducted in an inert atmosphere and a temperature range of from $-40°$ C to $+400°$ C $\pm\ 0\ 5°$ C A small window and a light source in the walls of the chamber allowed observation of the sample during the test

Mr H G Muller (Spillers, Ltd) briefly described results obtained with the *R*7 type rheogoniometer on wheat flour dough A cone of 2 5 cm diameter with an angle of 2° had been used at 24° C and the lower platen modified so that the sample could be surrounded by an annulus of solution to keep it at constant humidity It had been found that rotation experiments could not be conducted as the dough immediately rolled out of the gap Using oscillation experiments the effect of relaxation between the plates had been studied The doughs (56 0 per cent absorption, 2 5 per cent sodium chloride) had been mixed on a farinograph under constant conditions and allowed to relax between the platens from 15 sec to 120 min They were tested at 6 cycles/min and an amplitude of 1° 15′ This was the largest amplitude at which no normal pressure was discernible Elastic modulus and coefficient of viscosity, both of the order of 10^4 c g s , dropped during 120-min relaxation from $6 5 \times 10^4$ to $1 5 \times 10^4$ c g s , the largest reduction occurring during the first 45 min When the frequency was altered from 4 to 15 cycles/min at a relaxation time of 60 min , the modulus remained unchanged while the coefficient of viscosity decreased from $3 5 \times 10^4$ to $1 5 \times 10^4$ c g s At 15 cycles/min vibrations were observed in the instrument It was proposed that exchangeable cone and plate assemblies should be designed for substances requiring longer relaxation times

In reply, Mr King pointed out that certain plastics showed cavitation during tests, but as yet no other material had rolled up making rotation experiments impossible Exchangeable assemblies had been considered, but technical difficulties had so far prevented a solution He also suggested that perhaps dough should be regarded as a readily deformable solid, and testing programmes be formulated accordingly, as this material does not exhibit viscous behaviour during rotational tests with a cone and plate

On the day following the meeting, samples of human blood plasma, provided by Drs D'A Kok and J Mehrishi (University of Cambridge), and bovine synovial fluid, submitted by Dr J Harris (Orthopædic Hospital, Stanmore), were tested With the former no readings could be obtained Using a 1° cone of 7 5 cm. diameter at 30° C and a shear-rate of 360 sec^{-1} with the latter, no normal force was observed The viscosity was 0 0104 poises At 9 04, 57 and 180 sec^{-1} and a 2° cone no stress readings could be obtained The fluid broke down rapidly during the test A drop of it spilt during the experiment immediately corroded the cast-iron base of the instrument

The next meeting of the club will be held on October 29 at the Technological Research Station, Spillers, Ltd , Station Road, Cambridge, when Mr J F Hutton (Shell Research, Ltd) will speak on "The Rheology of Motor Oils" H G MULLER

STANDARDS IN SCIENTIFIC PUBLICATION

THE Scientific Publications Council met at University College, London, on May 31, to discuss "What is a High Standard of Scientific Publication and how is it Attained ?" Prof G W Harris (Maudsley Hospital, London) took the chair

Prof W V Thorpe (Department of Physiology, Birmingham) introduced the subject As editor-in-chief of the *Biochemical Journal*, he confined his remarks to periodicals publishing original scientific work, as opposed to reviews or monographs High standards in such journals imply publishing clear and accurate accounts of original contributions to research on which others can build How is this achieved ?

First, Prof Thorpe suggested the editorial board must refrain from selecting topical and interesting papers in preference to unexciting routine work, for what is dull to a man working in one field, may be of vital importance to those working in others The editors must guard against rejecting poorly written papers for that reason alone, since it is their duty to help inexperienced or foreign authors to describe their work in an acceptable style Since science is an international endeavour, colloquialisms, jargon and abbreviations should be avoided and care taken that unfamiliar terms are explained so that the meaning may be clear to foreign readers unversed in the language of publication For the same reason it is good practice to adopt, so far as possible, internationally agreed usage with regard to nomenclature and units, and a standard form should be used for references The International Union of Biochemistry recently set up a Commission of Editors of Biochemical Journals to encourage international agreement on such matters

Verbose and repetitive styles must be amended, since clarity and conciseness not only make the text more easily intelligible but also save readers' time and, incidentally, reduce the cost of publication Experiments should be so described that they can be repeated without further research or correspondence with the authors An author can assist in reducing the delay between submission and publication by preparing his contribution carefully so as to reduce editorial processing to a minimum and to eliminate any necessity for revising the manuscript

Editors should be vigilant to the point of suspicion and should check all statements which are readily susceptible to testing, for example, that totals are correctly added and that theoretical values for elementary analyses are correctly calculated

Ultimately the Editorial Board is the custodian of a journal's standards That of the *Biochemical Journal* does not itself prepare papers for the press—this is done by the editorial office staff—but exercises a judicial and very critical selection, communicates suggestions to authors on how to improve their manuscripts and, where necessary, explains why one has been rejected Only 15 or 20 per cent of papers submitted have to be refused Members of the Board are all active scientific workers and selected so as to provide collectively a balanced and critical judgment in many fields Before a paper is accepted, it is normally submitted to the scrutiny of at least two members of the Board, one of whom is a specialist in the subject of the paper, while the other provides the point of view of the general scientific reader If necessary an independent referee is consulted High editorial morale is achieved by frequent discussion and self-criticism, including periodical scrutiny of the statistics of time-lag in publication so that causes of delay may be identified and so far as possible removed

Mr A L Bacharach (*British Journal of Nutrition*, etc) explained that the subject arose when the Council was framing the clause in its rules relating to its aims, namely, to promote and maintain high standards in the dissemination of scientific information and in particular of scientific books and journals At that stage it seemed natural to try to define and prescribe for high standards in scientific publication Mr Bacharach declared his interest by pointing out that he had served on the editorial boards or publications committees of the Royal Institute of Chemistry and the Society for Chemical Industry, and of the *Analyst*, of the *British Journal of Nutrition*, *Acta Pharmacologica et Toxicologica* and others

Whether the editorial policy of a journal is controlled by a learned society, by a commercial publishing house or, like the *British Journal of Pharmacology*, by a learned society and a publisher jointly, the aim should always be the same high standard

Mr Bacharach was in substantial agreement with Prof Thorpe, but wished to extrapolate the argument a stage further He thought that editorial boards should not over-stress the letter at the expense of the spirit by, for example, undue punctilio about conforming to internationally agreed conventions, for these are never so important as consistency and clarity

The ultimate aim of editorial policy should be to foster a relationship of confidence between author and reader For this it is of the first importance to establish a high level of scientific content Papers should contain new information couched in an interesting style, free from ambiguity and expressed with clarity so that the work will be intelligible in theory and repeatable in practice

Mr Bacharach defined referees as all those specialists charged with judging the scientific value of a paper's contents, while editors he defined as those concerned with the form of a paper and its preparation for the press, and this irrespective of the way the terms may happen to be used by any particular publishing body Often the same people may be involved, but their functions are distinct

Some journals have recently been started with the special aim of securing rapid publication by the reproduction of authors' own typescripts using a photolithographic process In this case the editors' function is reduced to a minimum, and the onus rests with the referees The first requisite for critical standards of refereeing is that it should be possible to send a paper to any suitable specialist anywhere in the world, and at least two independent opinions should be obtained, at any rate before rejection It is the duty of a referee to steer a careful course between the Scylla of academic orthodoxy and the Charybdis of extravagant novelty The editor is concerned to secure a high standard of presentation in style and syntax and to eliminate all obscurity or illogicality, and he is fully entitled to take all necessary corrective action Mr Bacharach did not agree with those who hold that what an author writes is his own affair alone To fail to obtain high standards of presentation is to abdicate from the editorial function and to connive at the reduction of a journal's status

Mr Bacharach then directed attention to the enormous proliferation of scientific publications in recent times and proposed a touchstone of justification for the appearance of a new journal The rapid advances in science are continually blurring old boundaries and creating new disciplines The test of a new journal is whether it will enable work lying across the boundaries of former traditional fields to come to the attention of workers on both sides of the division, whereas its publication in existing journals might bring it to the attention of one or the other only The same criterion might be applied to the creation of new learned societies

Mr Bacharach wondered what could be done about certain new journals, produced not under the ægis of learned societies but for commercial interests, relying for their circulation on what amounts to moral blackmail of librarians Their publishers know that the mere existence of a work creates a demand for it, and their activities are detrimental to the interests of science in general, of libraries with limited space and funds, and of other more scrupulous publishers *A fortiori*, the proliferation of technical books containing scientific information of an ephemeral or incomplete character represents a growing threat to the whole system of communication in science

Finally, Mr Bacharach remarked that *Nature* and similar journals exist for the rapid publication of short accounts of important new advances The publication of most researches should wait until a complete account of the work is available The insistence on speed in publication is a pathological development in science the influence of which is generally bad, being almost entirely at variance with the maintenance of high standards

Dr C C N Vass (St Thomas's Hospital Medical School, London) thought that the judicious selection of referees suitable for each manuscript submitted was one of the most important responsibilities of the editorial board and Mr J C Graddon (assistant editor, *Philosophical Transactions* and *Proceedings of the Royal Society*) felt that anonymity of referees might be a decisive factor in securing impartial advice Mr P C Williams (Imperial Cancer Research Fund) pointed out that referees have different standards, and it was agreed that anyone whose standards were known to be too low—or too high—should not be consulted Mr Williams wondered whether zealous editing might not even afford some authors an unjustified reputation for exposition and, moreover, might encourage people to submit slipshod manuscripts Mr N L Harris (General Electric Co , Hirst Research Centre) thought that editorial changes should be confined to grammatical corrections and should not aim at creating a drab uniformity of style However, Mr Bacharach maintained that this was a bogy, editors in general have no time to edit style because they are all too frequently engaged in grappling with its absence

Dr C A Hogarth (Brunel College, Acton) asked what should be done with manuscripts betraying signs of having been rejected by other editors Mr Bacharach replied that some journals require a declaration that a paper has not been submitted elsewhere, but Dr R K Callow (National Institute for Medical Research, Mill Hill) recalled the well-known fact that Sir Hans Krebs's announcement of his work on the citric acid cycle—for which he was later awarded the Nobel Prize—was refused by an eminent journal, there might be many reasons for the rejection by a particular journal of a paper without any reflexion on its scientific merits It is then good editorial practice to refer an author to an alternative vehicle for publication Mr Graddon remarked that the Royal Society is frequently asked to accept papers which are too long and expensive for others to publish It is a valuable custom that all manuscripts have to be communicated through a Fellow of the Society, who should be able to criticize the presentation and act, to some extent, as referee before consenting to act as sponsor

Mr P J Edmonds (Publishers Association, Technical Group) applauded Prof Thorpe's arrangements for periodic meetings of editors, production staff and printers, he thought that many of the problems with which the Council is concerned arise through imperfect comprehension between those responsible for the scientific, literary, technical and financial aspects of publication While appreciating Mr Bacharach's feelings about the proliferation of books and journals, he thought that the remedy lies with librarians and library committees, who should be more selective Mrs Olga Kennard (editor, *Crystal Data*) said that the publication of candidly critical reviews in reputable journals is the greatest safeguard, but Dr A J Evans (librarian, School of Pharmacy, London) complained that even though economic considerations force librarians to be selective, reviews often appear too late to be of much assistance to them

A V S DE REUCK

THE FULMER RESEARCH INSTITUTE

AN open day was held at the Fulmer Research Institute on June 7 The occasion marked the fifteenth anniversary of the Institute's foundation and the completion of laboratory extensions

The chairman, Mr W R Merton, introduced the principal guest, Mr Denzil Freeth, Parliamentary Secretary for Science, who emphasized in a short address that the Ministry did its best to persuade industry that scientific and technological research is not only worth while, but is in fact economical and vital for progress, expansion and prosperity The reply was often that it was too costly to set up extensive laboratories and engage specialized staff to carry out particular pieces of research This was true, but it was to overcome this objection and to meet these needs that establishments where confidential sponsored research could be undertaken had been set up Mr Freeth congratulated Fulmer on the high quality of its staff and specialized facilities and said that he envisaged a great future for sponsored research

The new extensions to the Physics and Physical Metallurgy Laboratories provide approximately 3,000 sq ft of additional laboratory space, about half of which is basement accommodation Provision is made in the extensions to the Physical Metallurgy Laboratory for handling toxic materials, and in the extensions to the Physics Laboratory for housing additional X-ray diffraction units, together with a new *EM*6 electron microscope

In recent years, a high proportion of the work of the Physics and Physical Metallurgy Sections has been concerned with metals of importance in the field of nuclear power, such as uranium, zirconium and beryllium In unalloyed uranium the orthorhombic α-phase is stable up to 660° C and the anisotropic nature of the α-phase can result in dimensional instability of fuel elements in the reactor One way of avoiding this is by quenching dilute alloys from the β-phase region to give a fine-grained structure, free from preferred orientation The mode and kinetics of transformation of the β-phase are being investigated at Fulmer using hot hardness, thermal analysis, X-ray diffraction and metallographic techniques, the structure of the β-phase is also being studied

Another approach for overcoming fuel-element instability is to alloy the uranium to a greater extent to give the cubic isotropic γ-phase at fuel temperatures Basic information pertaining to the processes occurring when fuel elements are cooled has been obtained at the Institute by quenching various alloys at different cooling-rates to give a sequence of transformation structures between γ and α The physical properties, kinetics and mechanism of transformation of these alloys have been studied

Zirconium and its alloys are important as canning and constructional materials in water-moderated reactors The recent announcement by the United Kingdom Atomic Energy Authority of the projected development of the steam generating heavy water reactor makes the Institute's work on zirconium of particular interest The reactive nature of zirconium has necessitated the design of a high-vacuum, high-temperature X-ray camera for structural studies at temperatures up to 1,000° C The embrittling 'omega' phase has been studied in a number of binary zirconium systems and the nature of the omega phase and its derivation from the high-temperature body-centred cubic structure of zirconium have been determined

Beryllium has important applications as a nuclear and structural material by virtue of its low neutron-absorption cross-section and high strength/weight ratio, but its present use is limited by its inherent brittleness The deformation characteristics of beryllium have been studied at Fulmer, and the present work is concerned with the effect of minute amounts of impurities in beryllium It is thought that some impurities form precipitation-hardening systems with beryllium and the mechanism of precipitation in beryllium having an artificially high iron content is being studied by X-ray diffraction A specially designed X-ray diffraction camera for studying the structure of liquid metals was demonstrated Recent work has shown that the structure of liquid tin can be regarded as consisting of tetrahedra of grey tin in a random matrix Work on alloy systems has shown that liquids of certain alloys, for example, gold–tin, copper–tin and gold–gallium, exhibit a high degree of order, and X-ray diffraction work on these systems is being supplemented by density studies

Chromium is attracting considerable interest as a high-temperature material, but suffers from brittleness at room temperature This brittleness is thought to be associated with the presence of impurities and the Institute's fluoride process for electrodepositing purity chromium (10 p p m nitrogen, 200 p p m oxygen and 80 p p m hydrogen) is an important contribution in this sphere Exhibits included a 4-in diameter chromium ingot prepared at Fulmer by melting electro-deposited flakes in a consumable arc furnace, and extruded chromium bars

Use of molybdenum as a high-temperature material is restricted because of the ease with which it oxidizes and the volatility of its oxide At Fulmer, molybdenum is being coated with boron and silicon in an attempt to overcome this problem The sample to be coated is placed in a graphite reaction vessel surrounded with small pieces of boron (or silicon) The vessel is heated to an appropriate temperature and a slow stream of boron (or silicon) halide is passed through the system A lower halide is formed and reacts with the surface of the sample to form a boron or silicon coating Work is also in progress on the coating of another high-temperature material, graphite, with tungsten The graphite is heated in a stream of hydrogen into which tungsten hexafluoride is injected and a tungsten coating is obtained

The results of work on the causes of 'feathering'—an extrusion defect—in lead–antimony cable sheathing were shown The defect was found to be caused by melting of segregates of low melting-point during extrusion and was overcome in the laboratory by use of a central chill during extrusion

Work at the Thornton Research Centre of Shell Research, Ltd , and at Fulmer has shown that the resistance of pearlitic cast irons of the type used for cylinder liners of marine Diesel engines to corrosion by condensed sulphuric acid is related to the silicon content This work has aroused considerable interest since corrosion of this type is thought to be a major factor in the wear of engines Recent work at the Institute has been concerned with the effect of copper and nickel additions on the corrosion resistance of these irons The Corrosion Laboratory exhibits included accounts of work on corrosion fatigue, stress corrosion and the effect of anodizing variables on the corrosion resistance of anodized aluminium The corrosion-fatigue properties of high-strength aluminium–zinc–magnesium alloys are being studied with electrochemical polarization of the specimen It has been shown that increased fatigue lives can be produced by electrochemical polarization and various stages in the potential/time curves can be related to different cracking mechanisms The work is valuable in contributing to an understanding of the influence of sacrificial anodic coatings in corrosion fatigue A 'Slipping-clutch' axial-load fatigue machine of the National Physical Laboratory type, designed and built in the Institute's laboratories, was an item of special interest among exhibits of apparatus, and arrangements have been made to build these relatively inexpensive machines under licence for sale to outside laboratories

The discovery several years ago of superconducting alloys which exhibit superconductivity at very much higher critical fields than had previously been achieved was an event of considerable importance These alloys are now being considered for such applications as power transmission and for achieving high magnetic fields for nuclear fusion experiments The staff of the Process Metallurgy Section have successfully fabricated the superconducting alloys Nb_3Sn, V_3Ga and Nb/Zr, which tend to be brittle and difficult to handle, into a variety of forms required for electrical measurements

The Physical Chemistry Section specializes in the determination of thermodynamic data of high accuracy, exhibits included accounts of calorimetric measurements of heats of formation of inorganic fluorides, chlorides, bromides, nitrides uranium alloys and various binary metal oxide systems Boron trifluoride is of interest as a rocket propellent because of its high heat of formation Boron monofluoride can also be formed in reactions involving boron and fluorine, and the stability of this radical is being studied At high temperatures, radiation from gases plays an important part in heat transfer and emissivity data are therefore important for the design of equipment An apparatus designed and constructed at the Institute for measuring emissivities of gases at temperatures up to 1,000° C was demonstrated in the Physical Chemistry Section

The wear resistance of thin metal films for use in potentiometers is being studied at Fulmer The films are produced by evaporating nichrome alloy on to a glass substrate Potentiometer conditions are simulated by mounting the film on a turntable and making contact with a sliding probe Results of the present work show that the mechanical wear depends on the current in the sliding contact and the design of the probe and may be reduced by limiting the maximum voltage at the contact

The Institute has an Associated Electrical Industries *EM*3*A* electron microscope and an *EM*6 instrument is on order Various types of replica techniques were demonstrated in the electron microscope section and emphasis was laid on the use of reflexion techniques for examining solids Recent uses of the microscope include a study of the build-up of scale in oil-fired boilers Electron micrographs showed how fine oxide needles are first formed on metallic surfaces These afterwards grow and entrap ash particles forming a basis for the build-up of scale Electron micrographs were also shown of razor-blade edges, evaporated metal films and metal fracture surfaces, and there were examples of the use of the electron microscope in the study of precipitation in thin films

Recent research on the mechanism of age-hardening in aluminium alloys, a field in which the Institute's work is widely known, has been concerned with the effects of quenching and of heating to ageing temperature on the ageing characteristics of high-purity aluminium–copper alloys containing small ternary additions such as indium and magnesium A study of the influence of small ternary additions in magnesium–lead, aluminium–magnesium and various copper-base alloy systems has indicated that their effects can be rationalized in terms of atomic size factor, particularly where they modify the distribution of precipitate rather than its structure, and where they influence grain boundary phenomena and over-ageing

Creep fracture is often associated with the linkage of grain-boundary cavities formed during creep Work on the influence of small binary additions on cavity formation was exhibited Addition of titanium to chromium results in a finer distribution of cavities than in unalloyed chromium, and vanadium additions appear to prevent cavitation Creep cavities are frequently nucleated at non-metallic inclusions and the effect of small solute additions on formation of cavities in copper is being studied using high purity copper free from non-metallic inclusions

In recent work on the deformation characteristics of copper–zinc alloys, yield stresses of alloys with varying zinc contents and grain sizes have been measured over a range of temperatures, the structures of slip lines in alloys of varying zinc content have been studied by electron microscopy The results indicate that the changes in slip structure and the solid-solution hardening which occur on addition of zinc to copper can be attributed to segregation of zinc atoms to dislocations J COLE

PHYSICS RESEARCH BY THE AUSTRALIAN COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

THE annual reports of the Divisions of Metrology, Physics and Tribophysics of the Commonwealth of Australian Scientific and Industrial Research Organization covering the year 1960–61 are issued separately*. The Division of Metrology reports a busy year in all sections, but restriction of activities because of difficulties encountered in staff recruitment and of available workshop facilities. The interferometry section concentrated its efforts on work associated with the optical definition of the metre, and precise studies have been made of the spectral quality of various radiations under consideration as possible primary optical standards of length, the measurement of wave-lengths and wave-length shifts, and the transfer from wave-length standard to mechanical lengths standards. A report on this work was made at the Eleventh General Conference of Weights and Measures in October 1960. The Division's mechanical length standards are now established in terms of the new fundamental unit of the wave-length of krypton-86 orange light adopted by the Conference. In the Electronics Section the application of a moiré fringe system to replace the mechanically contracting style and scale in the equipment for the measurement of periodic errors in machines has been considered and some experimental work has been carried out on electronic circuits to simulate sensory processes. No progress has been made in the applied mechanics section with the provision for a primary standard for force, but new proving equipment has been obtained to augment the Section's range of such devices as proving rings. The theoretical and experimental study of vibration isolation has continued, and much activity is reported in engineering design analysis, including the preparation of instruction manuals and the organization of lectures for design staffs.

In addition to its responsibilities for the maintenance and development of standards of physical measurement in the fields of heat, light, viscometry and hygrometry, the Division of Physics has made important advances in three major research activities. Using techniques developed in the Division of Electrotechnology for the inter-comparison of capacitors, investigations of thermal expansion of various solids have been made down to liquid helium temperatures, enabling the electronic contribution to be measured for the first time. A simple method of zero-field paramagnetic resonance spectrometry has been developed and applied to sapphire and a number of paramagnetic salts, and the $\frac{1}{8}$ Å birefringence filter has been used to study the vertical velocity distribution over extended regions of the solar chromosphere. Developments of new instruments have included a sensitive triode flame ionization detector for use in gas chromatography, a Fabry–Perot interferometer with plates which are servo-controlled for parallelism, and a stellar seeing-monitor.

The Division of Tribophysics had its origin as a group studying war-time problems of friction and lubrication, but it has extended its investigations to include fundamental studies in the physics and chemistry of surfaces of solids and in metal physics. In most of the experiments large single crystals are used, and since clean metal surfaces are highly reactive two ultra-high vacuum systems (to pressures down to 10^{-10} torr) have been constructed in association with equipment for following surface reactions by means of a mass spectrometer. The 'atomically flat' surface obtained when a crystal is cut by a plane consists of flat areas separated by monatomic steps. The distribution of such steps and of kinks on the edges of the steps for any crystal cut by a plane in an arbitrary direction has been calculated and models constructed of a surface. Two effects caused by bombarding metal crystals with inert gas ions are being studied. Work has continued on the determination of arrays of dislocations in metals and on the electrical resistivity of dislocations. The results of measurements of stored energy and electrical resistivity have been used to calculate the resistivity of a dislocation in aluminium, copper, nickel and alpha brass. The resistivity of a dislocation was found to increase as the stacking fault energy decreased, but the magnitude of the increase did not suggest that stacking faults make a major contribution to resistivity.

All three reports include lists of staff and of their published papers.

THE NATIONAL INSTITUTE OF OCEANOGRAPHY, WORMLEY

THE annual report of the National Oceanographic Council* describes the work carried out by the National Institute of Oceanography during the year which ended on March 31, 1961. With improved recruitment of staff, the number in the scientific and experimental officer grades reached nearly 50, with about 60 supporting staff. The Institute's research vessel, R.R.S. *Discovery II*, remained in full commission throughout the year, working on a wide variety of projects, some cruises being joint ventures with other bodies, including the Universities of Birmingham, Bristol and Cambridge. *Discovery II* is rapidly approaching the end of her working life, and during the year under review much time was devoted to the design of a replacement. Since March 1961, the construction of the new ship has, in fact, been put in hand, and it is expected that she will be completed this autumn.

The research activities of the National Institute of Oceanography are aimed primarily at a better understanding of the physical and biological processes taking place in the sea. It is possible, in a review, to mention only a few highlights of the work being carried out. In pursuit of basic research on the generation of waves, a wave-recording buoy for use in the open ocean has been developed. It enables observations to be obtained by which the properties of the waves can be related to the structure of the wind flow over them. This work has a direct bearing on new theories of wave generation which have been put forward recently. Internal waves, which reach their greatest amplitude at an interface, or a region of steep density gradient some distance below the sea surface, are the subject of a new theoretical and observational study. Their presence becomes apparent in the vertical oscillations of isotherms, for example, or in movements of a sound-scattering layer.

Oceanic circulation continued to be one of the main fields of activity for the Institute, and a joint project was undertaken with the Woods Hole Oceanographic Institution, on deep-water movements in the Atlantic, near Bermuda. From observations extending over a number of months, it was found that the currents at 2,000 m. and 4,000 m. were both stronger and more variable than had been anticipated. The cause of such transient currents, with a time-scale of several weeks, has not yet been established, although possible theories are being considered. A variety of methods, including echo-sounding, horizontal echo-ranging and photography have been used in studies of the sea floor, in both shallow water and deep oceanic areas. In collaboration with the Department of Geodesy and Geophysics, University of Cambridge, the deeper structure of the ocean floor in the region of the mid-Atlantic ridge was investigated by magnetic and gravimetric surveys.

The increasing use of measurements of electrical conductivity as a means of inferring the distribution of density and salinity in the ocean has led to an international investigation being initiated of the relationship between these three properties. The Institute is taking part in this work, which also involves an examination of the relative proportions in which the major chemical constituents occur in sea-water from various regions.

On the biological side, the productivity of oceanic waters has continued to be one of the main fields of interest, and various instruments and techniques have been developed for studying light as a factor in production. One of the findings in the work on the distribution of organisms is that while some species appear closely dependent on the physical conditions in the water masses and on their movements, others show a marked independence of their physical environment. Research has continued on the life-cycles and population dynamics of whales and the application of the knowledge obtained to conservation problems.

The Institute continued to be directed by Dr. G. E. R. Deacon with Dr. N. A. Mackintosh as deputy director, in charge of the biological activities. Dr. J. N. Carruthers, well known for his work in physical oceanography, particularly on currents, retired from the post of assistant director on reaching the age limit, but continued to serve the Institute in a disestablished position.

Plans for the future growth of the Institute have been put forward in accordance with the recommendations of a conference held under the auspices of the Royal Society in November 1960. The National Oceanographic Council considers that an increase in real effort of 50 per cent during the quinquennium 1962–67 should be aimed at, involving the recruitment of 18 scientific staff and 40 in other grades. This would depend on the income being made available to meet a corresponding increase in the expenditure on the Institute and its research ship, which in the year 1960–61 amounted to £283,000. K. F. BOWDEN

A BIOLOGICAL PRINCIPLE AND ITS CONVERSE: SOME IMPLICATIONS FOR CARCINOGENESIS

By P. R. J. BURCH*

Health Physics Division, Oak Ridge National Laboratory†, Oak Ridge, Tennessee

SOMATIC mutations of one kind or another have often been suspected of contributing to carcinogenesis, and some recent evidence favours this view[1,2]. A variety of multi-stage mathematical models has been built on this basic supposition to account for the dependence on age of cancer mortality-rates[3].

Epidemiological evidence points to a marked inherited component in the ætiology of many malignancies, including leukæmia[4-6].

If the 'inherited component' can be equated with a (nuclear) gene mutation—and the commonest suggestion from the literature is of dominant inheritance with low penetrance—then if we assume a continuity of genetic information from the zygote to any nucleated somatic cell in the mature organism, it is difficult to avoid the following generalization and its converse.

(1) Where the ætiology of a given neoplasm involves somatic nuclear gene mutations, individual tumours of this kind will be found in which inherited mutations have substituted for somatic.

The converse principle should be valid.

(2) Where Mendelian inheritance of a neoplasm can be demonstrated, somatic mutation should also contribute to its genesis.

Exceptions to (1) can be imagined. Thus a particular allele present in a small proportion of cells may be tolerated in one type of tissue (to contribute to its ultimate malignant transformation), but distributed widely in another organ the same allele may have immediate lethal consequences. Inheritance of this specific mutation will therefore yield a non-viable karyotype, but arising *de novo* in an appropriate somatic cell, it could be carcinogenic. It is also conceivable that acquired immune tolerance[7] could develop to an inherited allele or alleles, whereas this would not be possible if the mutation occurred in a somatic cell of the immunologically competent individual

Although (1) and (2), exceptions apart, are almost self-evident, they do not appear to have been previously enunciated or incorporated in theoretical arguments, nevertheless, their implications could be profoundly important

An analysis of the ætiology of human leukæmias has been attempted using (i) the above principles, (ii) a multi-stage mathematical model which takes account of growth and permits the derivation of a somatic mutation frequency, (iii) a wide range of epidemiological and cytogenetic evidence The following conclusions have been drawn, the detailed derivation will be given elsewhere

(*a*) Leukæmias in childhood and adolescence generally arise from one or more cells containing one inherited[6] and two somatic mutations, an additional, primarily non-genetic, factor is required for the malignant transformation of such cells This can be either the 'stress' produced by the stimulated proliferation of leucocytes by normal growth and certain pyogenic infections, especially pneumonia[6,8] or infection by a leukæmogenic virus More complicated inheritance occasionally occurs A similar ætiology probably applies to many other malignancies of childhood and adolescence

The theory accounts for (i) the frequency of childhood leukæmia in multiple sibs[6], (ii) the 'anomalous' frequency of childhood leukæmia in uniovular twins[9], (iii) the ratio of childhood leukæmia incidence in mongols (trisomic or effectively trisomic for chromosome 21), to that in non-mongols[6,10], (iv) the ratio of leukæmia incidence in Videbaek's[5] 'leukæmic' and control families, (v) the reported increased incidence of childhood leukæmias and malignancies[6,11] (in genetic carriers) consequent on small doses (~ 1–10 rem) of pre-natal X-rays

(*b*) Chronic lymphatic leukæmia in adults mostly arises from one or more cells containing one inherited and three somatic mutations A generally small proportion (increasing with age) is entirely post-zygotic[6] in origin—arising from one or more cells with four somatic mutations, this is probably an ætiological feature of most spontaneous malignancies in adults Hyperplasia (meaning an excessive but non-malignant proliferation) of pre-leukæmic cells occurs, and this phenomenon is probably exhibited in the ætiology of all cancers where, in adult life, the age-specific incidence, properly corrected for cohort effects and latent period, is proportional to a power of age higher than 2–3 The hyperplasia could be, but in general is probably not, produced through viral infection Excepting certain malignancies in childhood and adolescence, a multi-focal origin for spontaneous tumours should generally be restricted to those that are preceded by a hyperplastic condition

(*c*) Chronic myeloid leukæmia in adults generally develops from a cell containing one inherited and two somatic mutations, together with the Ph^1 chromosome[1], which is regarded as being equivalent to a gene deletion A mutant gene can sometimes substitute for the Ph^1 chromosome

(*d*) In adults, acute leukæmias of all histological types, and lymphosarcomas, generally develop from a cell containing one inherited and three somatic mutant genes There is little or no hyperplasia of pre-leukæmic cells

(*e*) For all the above ætiologies, the calculated somatic and germ-cell mutation frequencies are closely similar, from about $(1–5) \times 10^{-6}$ yr^{-1}, and comparable to the somatic mutation frequency in sheep[12] and to the known spontaneous germ-cell mutation frequencies at various loci in mice[13] and in man[14] These conclusions are based on the assumption (following the bacterial investigations and conclusions of Kubitschek[15]) that latent 'point' mutations arise in a formed gene (rather than at replication) and that their expression can in certain circumstances be independent of mitotic rate With this point of view, it is convenient to express mutation-rates in terms of the following unit specific mutations (or alleles), per specific gene, per cell at risk, per annum

From the work, mainly of Videbaek[5] and Stewart[6], it is suspected that the same alleles that predispose to acute lymphatic and some stem-cell leukæmias also predispose to lymphosarcomas[6], certain pernicious anæmias, and certain cancers[5], furthermore, a different set of common alleles may be involved in chronic lymphatic, chronic and acute myeloid, and some stem-cell leukæmias, together with certain pernicious anæmias and some cancers[5] For each set of alleles, it is estimated that the proportion at birth of genetic carriers in the population of England and Wales is about 1 per cent Given the predisposing dominant inheritance, the penetrance in the form of a specific leukæmia is typically of the order of 10 per cent for a normal life-span of 70 years The penetrance for acute lymphatic and stem-cell leukæmias during childhood (0–9 years) is about 2–3 per cent

(*f*) Viruses of the appropriate specificity should theoretically be able to induce or assist in the induction of malignancies by at least five distinctive mechanisms, however, their ætiological role, when it occurs in human malignancies is complementary, or additional to gene mutations

(*g*) There is usually a long and variable interval between the emergence of a cell (the 'carcinogenic nucleotype') the nuclear constitution of which confers malignant potentiality, and its conversion into an actively malignant cell For radiation-induced leukæmias at Hiroshima, for example, the median latent period was about seven years[16,17] Where the malignant conversion of the carcinogenic cell is not effected by viral or hormonal agents, it is most probably produced through an immune reaction[17,18]

(*h*) At Hiroshima, radiogenic non-leukæmic malignancies[19] were almost certainly induced by a mechanism in which ionizing radiation simulated the spontaneous mutation process Spontaneous somatic mutation frequencies relevant to leukæmic and non-leukæmic malignancies appear to be similar Radiogenic leukæmias at Hiroshima and Nagasaki were probably induced through a basically similar ætiology, although a very high value for α the radiation mutation coefficient is deduced for large (~ 600 rems) very acute doses This value is about 2×10^{-6} mutations per specific gene per cell at risk per rem—in contrast to the more normal value of $1\ 5 \times 10^{-7}$ rem^{-1} obtained for the numerically important non-leukæmic malignancies However, in the fractionated X-irradiation of ankylosing spondylitis patients, at much lower dose-rates, the average value of α applicable to chronic myeloid and acute leukæmias is about 8×10^{-7} rem^{-1} These conclusions suggest that the 'leukæmic genes' exhibit the same type of mutational dependence on dose-rate and absolute (acute) dose as the germ-cell genes in pre-meiotic cells of mice[13]

There is a hint of a similar dependence in the case of non-leukæmic malignancies, although the statistics are poor It is probable that chromosomal aberrations (for example, the Ph^1 chromosome) are associated with some radiogenic leukæmias, and this may help to account for the high value of α If the value of α relevant to chronic lymphatic leukæmia is similar to that for non-leukæmic malignancies, this will explain why this type of leukæmia is rarely encountered[20] in connexion with radiation exposures In human radiation carcinogenesis, it is necessary to distinguish between the short- and long-term responses in genetic carriers and in others In the 'short-term response' the nuclear carcinogenic changes are completed at the time of irradiation, in the 'long-term response' the ultimate nuclear change is made afterwards through spontaneous mutation With the exception of the highest age-range ($>$ 60 years), it is concluded that most of the victims of radiogenic malignancies at Hiroshima up to 1958 were carriers, through inheritance, of a predisposing mutation

Predicted dose-response relationships (in good agreement with those observed) are complex, dose-rate dependent, and strongly age dependent, but they tend to linearity at low dose If, in chronic lymphatic leukæmias and in non-leukæmic malignancies, the 'carcinogenic genes' mutate at low dose-rates in a way similar to the recessive genes of pre-meiotic mouse germ cells[13], it is estimated that background radiation of 0 1 rem yr^{-1} should be responsible for $\sim$ 0 2 per cent of the spontaneous incidence of these malignancies If, however, the mutational process is independent of dose-rate, an upper limit of $\sim$ 1 per cent is obtained With the more radiosensitive chronic myeloid and acute leukæmias, there is good evidence of a dose-rate dependence, and background radiation may be responsible for $\sim$ 3 per cent of the spontaneous incidence

COMPLEX OF RIBONUCLEASE WITH A SUBSTRATE ANALOGUE, CYTIDINE 2'-PHOSPHATE

By DR. E A BARNARD and DR A RAMEL

Zoology Department, King's College, London, W C 2, and Physical Chemical Institute, University of Basle

THE direct examination of the complex of an enzyme and its substrate (true or virtual) is of interest in investigations of mechanisms of action Methods that have proved of value in particular cases include spectroscopy of complexes having characteristic absorption[1], equilibrium dialysis[2] and centrifugal stratification[3] This latter class was introduced by Velick *et al*, in examining complexes of coenzyme I with dehydrogenases[4] they sedimented the protein components in a preparative ultracentrifuge tube and analysed layers of the supernatants to deduce the binding We have made an examination, in the analytical ultracentrifuge *in situ* by use of absorption optics, of the migrating complex of ribonuclease (RNase) with a substrate analogue

Cytidine 2'-phosphate (2'-Cp) structurally closely resembles a substrate (cytidine 2',3'-phosphate), and is a powerful competitive inhibitor[5] Such inhibition does not necessarily imply specific binding at the active centre, but further evidence comes from the spectral change observed[6] near 260 mμ on mixing RNase and 2'-Cp This decrease in absorption is about maximal at equimolar proportions (at *p*H 5 6) (ref 6c) and may indeed indicate a unique interaction at the active centre, but to establish this the binding must be identified with the active centre region and the alternative excluded that other molecules of 2'-Cp are also bound without spectral consequences

A direct method of establishing the composition of the complex or complexes here is thus desirable The present availability of absorption optical systems (with the Spinco Analytrol or, as used here, the scanning system of Hanlon, Lamers and Schachman[7]) in the ultracentrifuge, offers the possibility of following, by boundary separations, specific enzyme-substrate type interactions, if the small component shows strong light-absorption (A use of absorption optics (Analytrol) for measuring weight average sedimentation coefficients of mixtures of methyl orange with serum albumin has been mentioned by Schachman[8]) The RNase case, as it turns out, is well adapted to such a measurement of complexes, in that the dissociation constants are such that free and bound molecules can readily be distinguished thus (although the protein absorbs in the same region) within the limited concentration range of nucleotide optically acceptable here, and without significant error from interaction boundary phenomena[9]

Fraction *A* was isolated from RNase (Armour) by chromatography[10] and exhaustive dialysis Carboxymethyl-ribonuclease (Cm-RNase) was prepared[11] at pH 5 6 with modifications[12b] in technique, and was homogeneous after chromatography[10] on '*IRC*-50' 2′-Cp was chromatographically pure on 'Dowex-1' (ref 13) The Spinco model *E* ultracentrifuge was used with the scanning ultra-violet absorption system of Hanlon *et al* [7] and a chlorine-bromine filter isolating lines near 260 mμ Scanner deflexion from a baseline is proportional to absorbance in the range (0–1) used here and was calibrated in each run by the increments given by known amounts of nucleotide The scan of the solution at zero time was checked in each experiment to avoid anomalous variations across the cell, and readings were corrected for the small 'background'

The protein in solvent (0 70 ml) in the cell was taken to 59,780 rev/min and the absorbance scanned then and at 16-min intervals thereafter After redispersion, known amounts of 2′-Cp were added in turn in very small volumes from an Agla micrometer syringe, each mixture being sedimented and serially scanned similarly (The slight sedimentation of 2′-Cp itself produced in time a shallow curvature of its boundary Adequate correction of the supernatant concentration of 2′-Cp for this lowering at the meniscus was obtained by utilizing the observation that beyond 80 min (when, also, the protein has sedimented well away from the meniscus) the height at the meniscus was a linear function of time in both the calibration (2′-Cp alone) and experimental runs The heights and slopes of these lines (fitted by least squares) were used to predict the height at the meniscus as corrected for 2′-Cp sedimentation, at a fixed time (112 min) in each run, by comparison with a calibration run with 2′-Cp, assuming proportionality to 2′-Cp concentration within this set)

For determination of $S_{20,w}$, sufficient accuracy for present purposes was given by determining the mid-point of each boundary at 11 intervals (to 176 min) and plotting the log of the displacement of this against time Good linearity was obtained for each run ($S D \leqslant 7$ per cent) and lines fitted by least squares were used in deriving (ref 14) $S_{20,w}$ For RNase, one run where the transport treatment[14] was simultaneously applied also gave a value for $S_{20,w}$ within the same range (Table 1)

Binding of 2′-Cp to RNase At a ratio of RNase to 2′-Cp of 1 1 ($3 4 \times 10^{-5}$ *M*), almost all the optically dense material sedimented together at a rate similar to that for RNase alone (Fig 1*A*) In contrast, at 1 2 ratio (Fig 1*B*) the supernatant showed distinct 260 mμ absorbance (that is, unbound 2′-Cp) corresponding to virtually all the added second equivalent At 1 3 ratio, again no significant increase was found in the ultra-violet-absorbing material migrating with the boundary (Fig 1*C*), while the supernatant concentration was doubled (Table 1) Hence only the 1 1 complex is formed appreciably in this range, and the binding is 90 per cent complete at 1 1 ratio even at these low concentrations A dissociation constant K_1 (see Table 1) for the first 2′-Cp molecule bound can, in principle, be readily obtained from such measurements, the accuracy here is determined by the error limits in reading the traces, the instrumental reproducibility and the sharpness of boundary of the protein studied, as well as by the strength of binding Analysis in terms of multiple alternative binding sites is not required here, any second binding is so weak, relatively, that only an order of magnitude of its lower limit can be estimated ($K_2 \geqslant \sim 10^3 K_1$)

Table 1 BINDING RATIOS, DISSOCIATION CONSTANTS AND $S_{20,w}$ FOR 2′-CP COMPLEXES AT 20°, pH 5 6

Protein	2′-Cp Protein	r	K_1 range (M)	$S_{20,w}$ (mean)
RNase	0	—	—	2 05 ± 0 19 *s*
($3 4 \times 10^{-5}$ *M*)	1 1	0 90	$2 0 \times 10^{-6}$ to $1 1 \times 10^{-7}$	1 72 ± 0 08 *s* (*P* > 0 05)
	2 1	0 99	$2 3 \times 10^{-6}$ to ~ 0	
	3 1	0 97	$4 5 \times 10^{-6}$ to $6 9 \times 10^{-7}$	
			Mean $K_1 \simeq 1 \times 10^{-6}$ (all readings, RNase)	
Cm-RNase	0	—	—	
($3 4 \times 10^{-5}$ *M*)	1 1	~0*		1 59 ± 0 09 *s*
	2 1	0 05†	$\geqslant \sim 10^{-3}$	

r, Moles 2′-Cp bound per mole protein *P*, Probability of difference (by *F* test) from $S_{20,w}$ value of RNase alone Ranges of K_1 values obtained from the limits of estimated uncertainty in the readings RNase-2′-Cp values are from means of 2 complete sets

* Exact value uncertain, due to change of background between runs, but r is small since certainly a very large part at least of the 2′-Cp did not migrate with the protein

† Precision rather low, due to the small difference involved

Binding of 2′-Cp to Cm-RNase Cm-RNase migrated very similarly to RNase, but with $S_{20,w}$ apparently rather lower (Table 1) At 1 1 ratio (Cm-RNase to 2′-Cp) virtually all the 2′-Cp remained in the supernatant, the behaviour being as in that illustrated by Fig 1*B*, and the same was true at 1 2 ratio (Table 1) Hence no binding of 2′-Cp was detectable and if any occurs *K* must be very much larger (estimated $K \geqslant \sim 10^{-3}$ *M*) than for RNase

Difference spectroscopy[6c] (using Cary model 11 and Beckman *DU* spectrophotometers) confirmed the difference spectrum[6c] of RNase mixed with 2′-Cp, relative to the sum of the components, and showed that RNase (0 08 m*M*) mixed with 4,5-dihydrouridine 2′,3′-phosphate[15] (2 0 m*M*, pH 5 8, 0 1 *M* sodium acetate, 25°) gave no such difference spectrum, in the range 250–290 mμ, neither initially nor after the hydrolysis Guanidinated RNase[16] (> 97 per cent inactivated, 99 per cent lysine guanidinated) gave the same difference spectrum (at 0 08 m*M*, pH 5 6 or 6 0) with 2′-Cp (0 09 m*M*) as RNase, and the same loss of it at pH 8 0 Fuller details will be reported elsewhere Similar measurements on our sample of Cm-RNase with 2′-Cp (each about 0 07 m*M*, pH 5 5, $I = 0 1$) have been made by Dr M Irie, who finds the maximal spectral decrease near 260 mμ is less than about 20 per cent of that given by RNase with 2′-Cp (Irie, personal communication)

Discussion It is clear that the boundary observed (Fig 1, *A–C*) represents, virtually entirely, a molecular species, the complex of RNase with the substrate analogue, containing one molecule of each K_1 is about 10^{-6} *M* and K_2 is negligible compared with this

In this complex sedimentation method, equilibrium might be disturbed by separation of the species[9,14], if the complex has an appreciably different *S* to

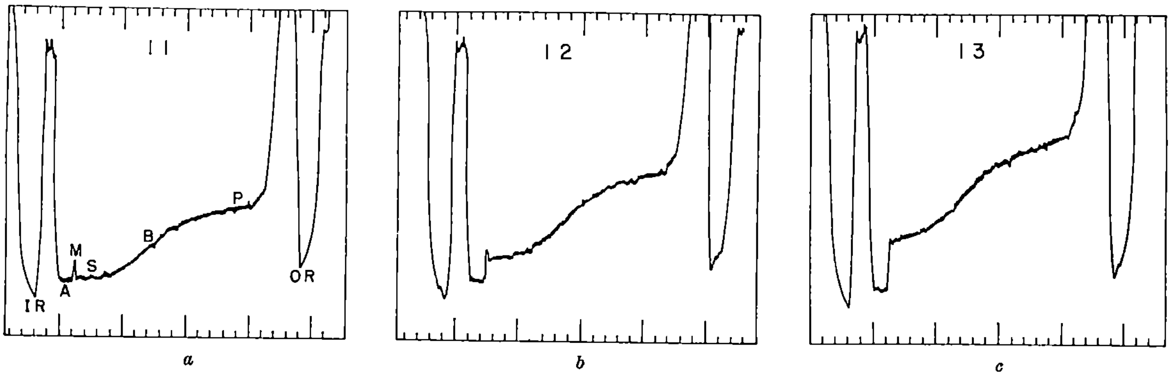

Fig 1 Scanner tracings (all at 112 min, speed 59,780 rev/min) Absorbance (heavy line) is plotted linearly (increasing upwards) by the scanner Distance from axis of rotation increases to the right (*a*) Sedimentation of RNase with 2′-Cp (one equivalent) *M*, meniscus, the short line (*A*) to the left marks absorbance level in air space above it *I R* , *O R* , inner and outer reference holes *B* is the boundary (broad, for RNase) of the sedimenting protein, plotted directly. *P*, plateau region Nearly all the absorbance, initially dispersed across the cell, is now accounted for behind the boundary, the trace is very similar to that for RNase alone, but with *B* and *P* higher here *S*, supernatant region, where residual absorbance (free 2′-Cp) is measured All readings are taken from a baseline (not shown) level, slightly below the level of *A* (*b*) With two equivalents of 2′-Cp About one equivalent is now sedimenting with *B*, as shown by absorbance in *S* region (*c*) With 3 equivalents About two equivalents are now accounted for by *S* height For Cm-RNase with 2′-Cp, at 1 1 the corresponding trace is very similar to that in (*b*), and at 1 2 to that in (*c*), but with *B* and *P* lower In all cases, protein is 3 4 × 10^{-5} *M*, solvent is 0 057 *M* sodium acetate (a compromise concentration, for stability in sedimentation without affecting binding), *p*H 5 60, temperature maintained at 20 0 ± 0 1°

that of the protein In the present case, the direct measurement of the free 2′-Cp and the simple stoicheiometry involved assure that the amount of free protein in a composite boundary must be small. The difference in *S* would need to be very appreciable for the conclusions to be erroneous here, especially at these concentrations well above K_1 $S_{20,w}$ for RNase and the complex (Table 1) showed no significant difference (at the 5 per cent level), if the small apparent difference was real, *S* decreases on complex formation and this would slightly inflate the 2′-Cp level in the supernatant[9,14], merely reinforcing the conclusion drawn and making K_1 slightly smaller

Technical refinements would be possible, for example, following the protein and the nucleotide by differential absorptions, comparison of *S* values more precisely (it would be of interest to know if the apparent slight decrease in *S* of the complex could be real, due to some configurational change), and more detailed investigation of *K*, but these results are adequate for the present purpose and establish a single strong binding as the basis of the spectral change, which may now be utilized, conveniently, for further study of the interactions (Confidence in the reliability of the measurements (which required only 330 μg protein per experiment) is reinforced by the reasonable agreement of the $S_{20,w}$ value with those found conventionally for RNase, extrapolated to similar protein concentration (close to 1 90), and by the contrasting distributions observed under identical conditions with RNase and with Cm-RNase, differing only at one residue and in activity) The usual Analytrol system can also be used similarly The value of K_1 agrees with that found from enzymic inhibition by 2′-Cp (ref 17) (for example, 4 5 × 10^{-6} *M*, at *p*H 5 6, $I = 0\ 1$ (ref 17*a*)) and by protection from urea unfolding[12], and is consistent with the spectral data at *p*H 5 6 (ref 6*c*)

Both observations made on Cm-RNase appear to disagree with that of Mathias *et al* [6b,18a], who reported unaltered interaction[18b], but support that of Hummel *et al* [6c], each based on the spectral criterion The derivative used here was homogeneous, inactive and contained one carboxymethyl group per molecule (by labelling with carbon-14) (A much weaker binding, only, might remain and might not be apparent in the sedimentation run, this must be investigated further)

Evidence available on the complex of 2′-Cp with RNase can be summarized (1) Only one molecule of 2′-Cp is bound with high affinity, as shown by complex sedimentation, by extent of spectral change[6c] or inhibition of urea denaturation[12], or by a recent, concurrent equilibrium dialysis measurement[17a,19] (2) This binding must be in the active centre region, from its loss in Cm-RNase (where, also, orthophosphate affinity is much reduced[12]) and from the strong competitive inhibition (3) The *p*H-dependence of binding[6c] is similar to that of substrate binding[20] The decrease in binding from *p*H 5·6 to 8 cannot be due to lysine groups, since this is also shown after guanidination At least one histidine appears to be involved, and the Cm-RNase evidence presented suggests histidine residue 119 (ref 11) is part of the binding site Unfolding evidence shows the 2′-Cp site is composite and across more than one chain[12] (4) Conversely, Cp binding prevents the attack of bromoacetate at histidine 119 (ref 11) (5) A specific absorption decrease near 260 mμ accompanies the binding of Cp or Up (ref 6c), but is absent in the hydrogenated Up compounds (which also bind well[20]), presumably it arises from an interaction of the ring with the enzyme In the guanidinated protein it is seen, significantly, that this binding can be separated from catalytic activity

Further results on and a molecular interpretation of the binding of inhibitors and of substrates to RNase will be presented elsewhere

Much of this work was performed at the Virus Laboratory, University of California, Berkeley, during the tenure of (E A B) a fellowship of the Rockefeller Foundation, 1960–61, and of (A R) a U S Public Health Service fellowship We thank Dr H. K Schachman for the use of the ultracentrifuge and scanner, Dr H Fraenkel-Conrat for the provision of facilities (to E A B), Drs M Irie and C A Dekker for providing the results of spectral measurements made on our sample of Cm-RNase, Dr J P Hummel for the communication of his results prior to publication and Mr D C Teller for assistance

QUANTITATIVE EVALUATION OF HUMAN CHORIONIC GONADOTROPHIN IN PREGNANCY URINE

By P. G. LYNCH and HERTA SCHWABACHER

Group 9 Laboratory, Peace Memorial Hospital, Watford

A QUANTITATIVE evaluation of human chorionic gonadotrophin (HCG) would be most valuable Methods have recently been described by Brody and Carlstrom[1-3], McKean[4] and Wide and Gemzell[5] In our hands the hæmagglutination test developed by the last-named authors failed to give constant results and was abandoned

It seems worth while, because of its potential clinical applications, to record our findings based on a complement fixation test for the determination of urinary HCG

Rabbits received by subcutaneous injection up to 3,300 I U of 'Pregnyl' (Organon) admixed with sterile Ramon's adjuvant[6] The injections were spaced out over a period of 16 weeks

Titration of HCG antiserum was found to be impracticable if 'Pregnyl' was used as the antigen At low concentrations, no fixation of complement was obtained and if higher concentrations were used the material was found to be anti-complementary HCG as described in the addendum or HCG obtained from the Department of Biological Standards, National Institute of Medical Research, London, proved to be satisfactorily antigenic Complement was used at 3 minimal hæmolytic dose (MHD) strength in all tests HCG used as antigen was found to give satisfactory results if used at strengths of 24, 12 and 6 I U The HCG antiserum was found by complement fixation to have a final titre of 1 in 8 using 6 I U of standard HCG as antigen in the test

For titration of urinary gonadotrophin the urine, preferably a first-morning specimen, is concentrated according to Scott's technique[7] and the concentrate accurately neutralized before being used as antigen The urine extract so prepared is stored at ± 2° C before testing and there seems to be no appreciable loss in HCG activity in extracts kept at this temperature for as long as seven days

Throughout the test 0 2 ml volumes of each reagent are used The urine extract is put up in a series of doubling dilutions from neat to 1 in 64 The normal controls are set up and the urine extract is tested for anticomplementary activity at strengths of neat, 1 in 2 and 1 in 4 In our experience, so far, any anti-complementary effects were diluted out at urine extract dilutions of 1 in 2 so that it is permissible to argue that any fixation of complement in the test series beyond this point is due to the presence of HCG At the end of each complement fixation test all the tubes are centrifuged and the end-point is taken as the final tube showing a button of erythrocytes

The complement fixation test already described here is being applied to rhesus-negative mothers in the third trimester of pregnancy, when it is hoped to confirm Scott's findings[8] that the larger than normal placenta of severely affected rhesus infants secretes an excessively high level of HCG Thus a high titre of HCG obtained in the complement fixation test and reported to the obstetrician at 32 weeks might well aid him in the decision to induce labour at the earliest possible moment

A full report on HCG titres found in the urines of rhesus-negative mothers with antibodies will be presented at a later date

It has proved impracticable to use the complement fixation test described here on pregnancy serum There are several possible explanations why this is so (1) HCG may be altered or destroyed by heating the serum at 56° C to inactivate complement, (2) the amount of circulating HCG may be too small to detect by ordinary means and is only concentrated by excretion in the urine, (3) HCG may be altered or destroyed by serum enzymes if there is a delay in separating off the serum

The HCG antiserum already described was subjected to immunodiffusion on cellulose acetate strips and by the plate method of Elek[9] and Ouchterlony[10] Precipitation lines were not obtained by either of these methods Immunoelectrophoretic investigations are being made

It is interesting to compare the results of the complement fixation test with biological pregnancy tests In a few instances (Table 1) it has been possible to compare results with the Hogben test performed on suitable urine dilutions The compari-

Table 1 COMPARISON OF COMPLEMENT FIXATION TITRES (CFT) WITH HOGBEN TITRES IN NORMAL RHESUS POSITIVE PREGNANCY URINES

Urine Ref No	Duration of normal pregnancy in weeks	HCG I U per ml extract CFT	HCG I U per ml extract Hogben*
1659	32	240	280
930	14	480	250–560
1412	4	30	28
1220	48	120	112
1952	N I	60	28
1974	N I	30	28
1978	N I	60	28
926	N I	30	28

N I , no information to hand as yet

* Minimal reacting dose = 28 I U per ml equivalent to 70 I U HCG per 2 5 ml for a 70-gm *Xenopus laevis*

son is somewhat crude and no correlation of figures has been attempted owing to the difficulties of performing quantitative bio-assays on large groups of animals

Conclusions Provided two *Xenopus*, known to be fully sensitive, receive 2 5 ml of each dilution of extract, the Hogben biological reaction compares well with the CFT

Addendum We thank Dr B M Hobson of the Usher Institute, Edinburgh, for the method of preparation of human chorionic gonadotrophin described as follows

Urine is obtained from the ante-natal clinic and pooled to give a final volume of 10 litres or more The urine is then filtered through a Buchner funnel fitted with two or three thicknesses of Whatman No 40 filter paper, which has been wetted by first dipping it in the urine Filtration is under suction (RB_4 via trap flask), and may have to be repeated if the first filtrate is not clear

The filtrate is measured and to each litre of filtrate is added 5 ml of glacial acetic acid while mixing thoroughly The *p*H of the filtrate is adjusted to 4 2–4 4 with hydrochloric acid or sodium hydroxide using bromophenol blue as indicator Test samples are returned to the filtrate 50 c c of a saturated solution of benzoic acid in acetone are now added to each litre of filtrate It is important at this stage to stir thoroughly so as to avoid surface precipitation The resulting mixture is allowed to stand overnight in the refrigerator

The following day, the supernatant fluid is decanted into a clean vessel The benzoic acid deposit is transferred into a Buchner funnel fitted with No 40 filter papers and the supernatant fluid is sucked through it twice, rinsing out the remnants of benzoic acid into the funnel Suction is continued until the powder is dry and cracking out, then the filter is removed and the filtrate saved for repeat extraction

The resulting powder is scraped off on to clean paper and chopped finely with a knife It is next transferred to a glass cylinder and suspended in an excess of acetone The deposit is allowed to form overnight in the refrigerator

Next day the supernatant fluid is decanted into a stock benzoic acid solution bottle The powder is transferred to a clean container and is stored in excess of acetone at 0°–4° C until required

The product may be purified by washing 4 or 5 times with acetone until no benzoic acid remains A clean glass slide dipped in the solution will detect traces of benzoic acid remaining, by forming an opaque film on the glass surfaces Washing is conveniently done by centrifugation

The purified powder should be dried in a desiccator to drive off the acetone It is then ground finely in a Griffith's tube and stored in a desiccator at room temperature until required The final preparation should be white in colour and is said to retain its potency for up to three years

AN ELECTRON SPIN RESONANCE STUDY OF THE ALKALINE DEGRADATION OF 2-METHYL-1,4-NAPHTHOQUINONE

By DR THOMAS C. HOLLOCHER, jun.*
The Adolphus Busch III Laboratory of Molecular Biology, Washington University, St Louis
AND
DR MORTON M WEBER
Department of Microbiology, Saint Louis University School of Medicine, St Louis, Missouri

THE transport of electrons from the level of reduced diphosphopyridine nucleotide (DPNH) through the cytochrome pathway in particles of *Mycobacterium phlei* involves the participation of vitamin K_1 or a naturally occurring naphthoquinone[1] Using the electron spin resonance technique[2,3], a naphthosemiquinone has been identified as a reactant in these oxidation-reduction systems[4] With this DPNH oxidase and the soluble DPNH-2-methyl-1,4-naphthoquinone reductase systems of *M phlei*, we find that the concentrations of naphthoquinone free radicals are strongly dependent on *p*H (ref 5) In examining the causes of these *p*H effects, some of which are not related to enzyme activity, we observed that 2-methyl-1,4-naphthoquinone undergoes a rapid degradation in alkaline aqueous solutions by a reaction which leads to the appearance of stable free radicals in extremely high yields These observations and a postulated reaction mechanism are reported in this article The reaction imposes difficulties in the study of biological redox reactions of 2-methyl-1,4-naphthoquinone even at moderately high *p*H values[5]

The degradation was carried out in the following manner Highly purified 2-methyl-1,4-naphthoquinone in ethanol or as the solid is added to an aqueous or aqueous ethanol solution of 0 12 *M* potassium hydroxide in an amount sufficient to make

---

* Present address Graduate Department of Biochemistry, Brandeis University, Waltham, Mass

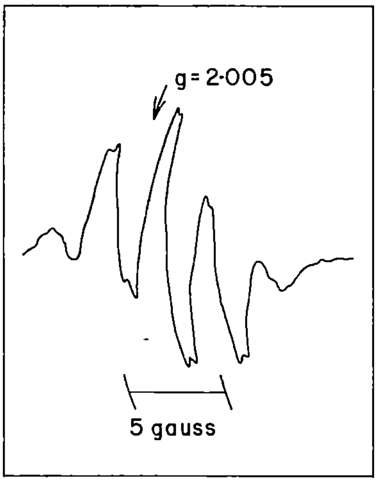

Fig. 1. Electron spin resonance spectrum obtained during the alkaline degradation of 2-methyl-1,4-naphthoquinone. 2-Methyl-1,4-naphthoquinone concentration is 2.5 m*M* at a *p*H of 12.5, modulation amplitude is 0.1 gauss, sweep time is about 1 min., and the time constant is 0.1 sec. Spectrum was taken about 3 min after mixing. The g-value mark and field scales were established using potassium peroxylamine disulphonate in sodium carbonate solution. The magnetic field increases from left to right in the figure

the final concentration of naphthoquinone from 2.5 to 10 m*M*. The cuvette containing the mixture is placed in the electron spin resonance spectrometer immediately after mixing. The first observation is made within 2 min., and observations are continued for as long as necessary. All spectra are taken at room temperature using a frequency of 9 kmc./s and a magnetic field modulation frequency of 1 mc./s.

Electron spin resonance signals, as shown in Fig. 1, appear immediately, intensify rapidly, and reach a maximum within about 10 min after mixing. Once the maximum value is reached, the signal intensity decreases very slowly under anaerobic conditions with a half-time of several hours. The addition of oxygen to the solution leads to a rapid disappearance of the signal.

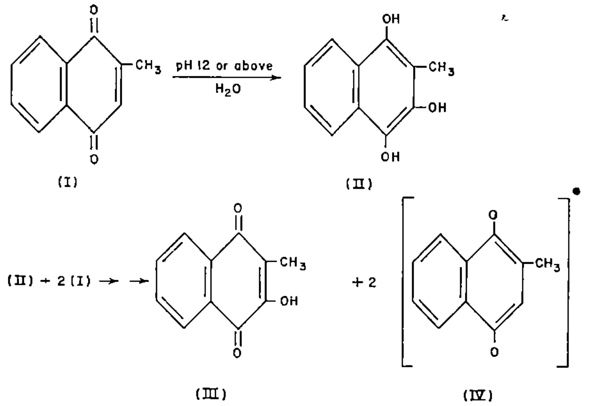

Fig. 2. Proposed mechanism for the formation of a free radical during the alkaline degradation of 2-methyl-1,4-naphthoquinone

The signal centres at $g = 2.004 \pm 0.001$ and consists of five hyperfine lines with intensity ratios of approximately 1 : 4 : 6 : 4 : 1 and with separations of 2.5 ± 0.2 gauss. Each of these five lines is further split into five lines with separations of 0.6 ± 0.1 gauss. Because of appreciable magnetic field inhomogeneity, these latter lines are not well resolved in Fig. 1. The characteristics of these electron spin resonance signals and their hyperfine splitting separations are identical with those described by Wertz and Vivo[6] and by Adams *et al.*[7] for the 2-methyl-1,4-naphthosemiquinone radical formed by chemical reduction.

Estimates of free radical concentrations were made by comparison with manganous ion standards[8]. These estimates were made with a precision of approximately 30 per cent and indicate that maximally 0.5–0.8 on a mole basis of the original 2-methyl-1,4-naphthoquinone is converted to the semiquinone radical.

These findings suggest that in the absence of an added reducing agent, 2-methyl-1,4-naphthoquinone or a derivative thereof must serve as its own one-electron reductant to provide a stable semiquinone

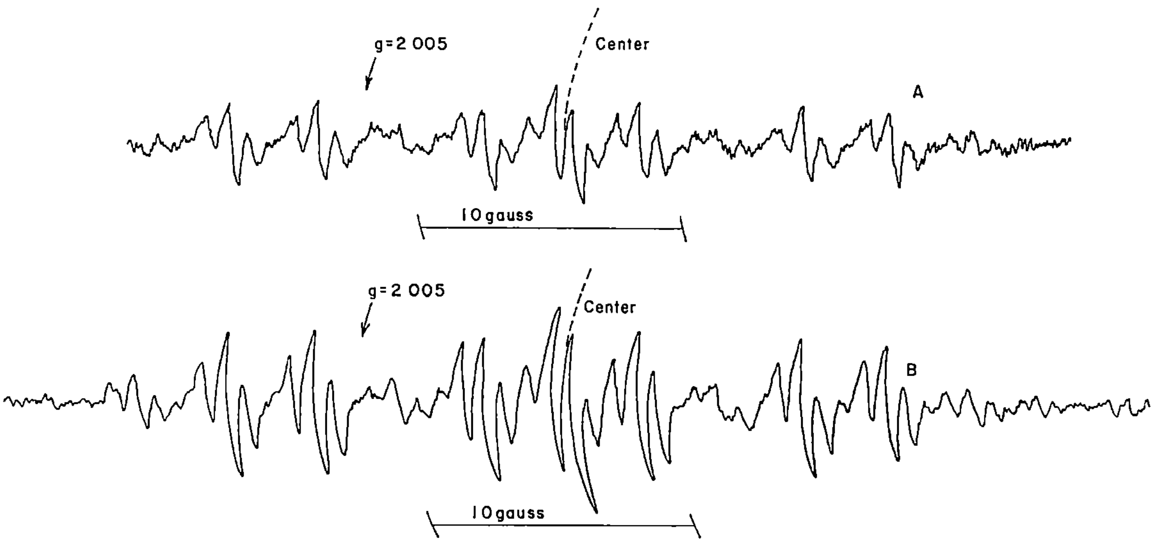

Fig. 3. *A*, high-resolution spectrum obtained with the products of the alkaline degradation of 2-methyl-1,4-naphthoquinone at *p*H 14, following reduction by $Na_2S_2O_4$ and subsequent partial reoxidation by oxygen. Original concentration of 2-methyl-1,4-naphthoquinone is 10 m*M*, modulation amplitude is 0.03 gauss, sweep time is 15 min., and the time constant is 1 sec. *B*, high-resolution spectrum obtained with 2-methyl-3-hydroxy-1,4-naphthoquinone at *p*H 14, following reduction by $Na_2S_2O_4$ and subsequent partial re-oxidation by oxygen. 2-Methyl-3-hydroxy-1,4-naphthoquinone concentration is 10 m*M*, instrument conditions are the same as in Fig. 3*A*. The g-value marks were obtained as in Fig. 1 and the field scales were established using calcium xanthone in tetrahydrofuran. The magnetic field increases from left to right in both Figs. *A* and *B*

in high yield A reasonable mechanism for the reaction is illustrated in Fig 2 2-Methyl-1,4-naphthoquinone (I) undergoes a 1,4 addition of water in alkaline solution to yield 2-methyl-3-hydroxy-1,4-naphthoquinol (II) The lower oxidation-reduction potential of (II) (ref 9) then permits the transfer of electrons to (I) with the formation of 2-methyl-3-hydroxy-1,4-naphthoquinone (III) and 2-methyl-1 4-naphthosemiquinone (IV) The semiquinone of (III) is apparently very reactive, and is not observed by the electron spin resonance technique during the reaction The radical observed (IV) decays only very slowly, presumably through redox dismutation, to yield (I) and 2-methyl-1,4-naphthoquinol or through dimerization The theoretical maximum yield of (IV) is 0 67 of (I) on a mole basis and is in agreement with the range of yields found

Oxygen rapidly oxidizes (IV) to (I) and results in the conversion of (I) to (III) in high yields That (III) is the final product of the alkaline degradation of (I) is confirmed by the identity of the high-resolution electron spin resonance spectra shown in Fig 3*A* and *B* Fig 3*A* represents the electron spin resonance spectra obtained when the product or products of the reaction, following oxygenation, are reduced with sodium hydrosulphite or sodium borohydride, in alkaline solution, and then partially reoxidized by oxygen. The results in Fig 3*B* are obtained when authentic (III) is similarly reduced and partially reoxidized These spectra are identical except with respect to amplitude and reflect differences in concentration only

In addition, the final product of the alkaline degradation of 2-methyl-1,4-naphthoquinone after extensive oxygenation is red-brown in colour in alkaline solutions, exhibits characteristic spectral changes as a function of *p*H, and is exceedingly stable in alkali These properties are consistent with our belief that the product is a hydroxylated naphthoquinone, specifically 2-methyl-3-hydroxy-1,4-naphthoquinone

This work was supported by grants (to B Commoner) from the Office of Naval Research and grant *C*–3983 from the National Cancer Institute, Public Health Service and grant *E*–3046 (to M M Weber) from the National Institutes of Health, Public Health Service We thank Dr Barry Commoner, who made this investigation possible We also thank Dr S I Weissman of the Department of Chemistry at Washington University for his co-operation and assistance in obtaining the high-resolution electron spin resonance spectra
